## EXECUTIVE SUMMARY

Over many years the Australian Geological Survey Organisation (AGSO), and its predecessor the Bureau of Mineral Resources, Geology and Geophysics (BMR), has acquired wide-angle seismic profiling data to determine velocity structures of geological features within various minerals and petroleum provinces. Wide-angle seismic profiling is a technique used where the shot-to-receiver offset is significantly greater than the target depth, e.g. for target horizons at 10 km the shot-to-receiver offset may be in the range 0-100 km. Basic information on the various surveys is commonly contained in operational reports written on each survey and published as AGSO (or BMR) Records.

With the rapid increases in the amount of data acquired in recent years as data acquisition methods have improved and the resolution of geological structure has become more demanding, it has become impractical to publish all the data from surveys in hard-copy form. Basic information such as recording station locations, shot data, shot times, instruments used, etc., is now stored in computer data files on various media. Hence there is a need to develop a database system to keep track of all the basic survey information.

This Record describes an AGSO wide-angle seismic profiling database that has been established using Microsoft Access<sup>®</sup> software which should enable users to locate and access basic survey information and data. It has been set up in such a way that it can be modified and improved with the addition of future data and new "fields" of information as required. The current database includes more recent surveys in the Browse Basin and Otway Basin. Survey data are accessed using a unique identifier for each survey (based on the date of firing the first shot). The scope of data being accessed will improve with the addition of older survey data. It is intended that database information and the computer data files be archived at regular intervals on a CD-ROM format.

## INTRODUCTION

Large wide-angle seismic profiling data sets acquired by the Australian Geological Survey Organisation (AGSO) over many years warrant an adequate archival system. The current practice of storing data files on the local network needs to be revised in the light of an ever increasing volume of data. Other means of long term storage are being considered, eg. CD-ROMs, Optical Disks, etc. Whichever way the system develops, the users will have to know where the various data sets are located and how to access them. A unified database containing all the relevant information for a particular survey can provide a solution to this problem.

As it stands, the process of converting analog seismic records to digital format is quite complex and involves generation of a large number of files. Over many years, various Fortran programs have been written to further streamline the digitising process and limit data duplication. Survey parameters, such as station locations and operating times, traverse information, distances and azimuths, are currently stored as individual files on the DATA8 disk of the AGSO ONSHORE Server. These files follow various naming conventions and are therefore not very easy to identify or access. The database will store all the survey information and will allow users to quickly identify where the data files are located and what processing steps have been applied to the data. The system will also allow queries on recorder operating times, shot distances and azimuths, first break picks, etc. This Record describes a relational database model, specifically designed to accommodate wide-angle seismic data sets acquired by analogue or digital seismic recorders, both onshore and offshore (ocean bottom seismographs).

## RELATIONAL DATABASE MODEL

Microsoft Access<sup>®</sup> is a commercial relational database package for the PC Windows environment. Various commercial textbooks describe MS Access<sup>®</sup> and its use. It organises data in TABLES, which form the basis of the relational structure. Different tables hold data which describe specific objects, like a seismic recorder or station. The purpose of having tables is to minimise duplication of fields in a database. It is easier to link two tables by a common field rather than to duplicate information into a single large table. This linking relates tables to each other, hence "relational database".

Access<sup>®</sup> database files have a \*.MDB extension. Upon entry, the user sees a folder window listing all the tables in the database. Double clicking on a table opens it and displays the data in the form of a spreadsheet. Fields in the tables can be updated and therefore if one wants to view data rather than change it, FORMS provide a better alternative. Forms can be made "read only" to prevent users from changing something by mistake. Forms can also be customised, so that users can filter data in a table according to certain parameters. Forms can be accessed by clicking on the form folder. Output from the form can also be viewed as a spreadsheet table and can be downloaded into Excel or a text file. Other folders in Access<sup>®</sup> contain QUERIES, REPORTS, MACROS and MODULES. QUERIES can select and update data from various tables; REPORTS generate written summaries of data within a given table. MACROS and MODULES run internal and external tasks (written in Visual Basic). In short, the system can be developed further to accommodate the various needs of its users. The interface can also be made more user-friendly without affecting existing data structures.

## WIDE-ANGLE SEISMIC DATABASE STRUCTURE

SURVEYS.MDB is a wide-angle seismic profiling database which contains information on the recent surveys conducted by the Land Seismic Group of the Australian Geological Survey Organisation.

The main table, **SURVEYS**, contains basic parameters for a given seismic:

- *SurveyNo* (commonly derived from the date of the first shot)
- *MarineID* (corresponding marine survey number, if applicable)
- *SurveyName* (usually giving location and year)
- *Seismic Method* (onshore, offshore or both)
- *Country*
- *State*
- *MapSheet* (1:1,000,000)
- *GeologicalProvince*
- *StartDate*
- *EndDate* (UT Date)

The corresponding form also displays number of recorders, stations and traverses (these are calculated from other tables). The total number of records (surveys in this case) is displayed at a lower left of the form. To navigate through the records, click on the arrow buttons at the bottom right of the form (PageUp and PageDown keys do the same). All other tables are linked to *SURVEYS* table by a *SurveyNo* field (ie. there must be an entry in the *SURVEYS* table before data can be entered in other tables).

Table **DATAARCHIVES** is a catalogue showing locations of digitised shot data. The fields are:

- *SurveyNo* (linked to *SURVEYS* table)
- *StationNo*
- *TraverseNo*
- *ClockDrifts* (Yes/No field showing if the archived data was corrected for a recorder clock drift)
- *TapeSpeed* (Yes/No field showing if the tape playback speed corrections were applied)
- *Cracked* (Yes/No field showing how the data is stored - in cracked format (individual shot files) or in uncracked format (large files containing many shots))
- *Picked* (Yes/No field showing record section first break picking status)
- *Modelled* (Yes/No field showing if the data was modelled by a ray tracing programs),  
*ArchivePath* (network path where the data is located)
- *FileName* (name of the archived data file(s))

At the time of writing, all refraction files reside on the L:\ drive (DATA8 ONSHORE), but in due course they will be moved to another storage medium. Contents of the *ArchivePath* field can therefore be updated to show CD-ROM volume number or other type of ID field can be added to the database. Form *DATAARCHIVES* allows users to query the locations of the data and to find out its processing stage. *QueryDataArchives* command button runs a filter on the contents of the table with

a given survey and station number. Other queries can be written, selecting data which hasn't been clock drift corrected, etc.

Table **RECORDERS** contains basic information on the recording units used during refraction seismic surveys. Data fields are:

- *SurveyNo*
- *RecorderNo*
- *RecorderBrand* (brand name of the recording unit, eg. PI, AKAI, TANDBERG, etc.)
- *RecorderType* (analog, digital, etc.)
- *ComponentsRecorded* (seismic components recorded, e.g. vertical, transverse, radial, hydrophone)

Records are grouped by survey number (not recorder number, since recorder numbers may be identical for different types of units used). Again, the corresponding form provides a query filter.

Table **RECTIMES** contains operating times of recording stations. Those times can be in different time zones (as long as there is a corresponding entry in the *TIMEZONES* table). The fields are:

- *SurveyNo*
- *StationNo*
- *RecorderNo* (included here because one station can have many recorders operating at various times)
- *GainSetting* (gain setting of the recorder, which can be set to *different* values at various times)
- *Attenuation* (used to obtain net gain value)
- *FilterSetting* (it can also be different at different times)
- *TimeZone* (time zone of the recorder, linked to the *TIMEZONES* table)
- *DateOn* (includes day and time in 24hr clock)
- *DateOff*
- *ErrorOn* (comparator error readout for analog clocks)
- *ErrorOff*

Form *RECTIMES* shows calculated fields of net recorder gain and UT operating time. *QueryRecorderTimes* command button selects recorders for a particular survey.

Table **SHOTDIST** contains distance and azimuth data from shots to recorders. The fields are:

- *SurveyNo*
- *StationNo*
- *TraverseNo*
- *ShotpointNo*
- *Distance*
- *Azimuth*

*SurveyNo*, *StationNo* and *TraverseNo* identify a particular distance file and have to be added in Excel prior to database import. *ShotpointNo*, *Distance* and *Azimuth* are imported directly from a *file* used in digitising. *QueryShotDist* on *SHOTDIST* form selects a group of records based on survey, station and traverse number.

Table **SHOTPOS** provides locations and UT times of individual shots. It may duplicate already existing database structures for the marine data; table **TRAVERSES** gives start and end times of the lines, and can be used for land data also (with a position field added). The fields are:

- *SurveyNo*
- *TraverseNo*
- *ShotpointNo*
- *Latitude*
- *Longitude*
- *UTDate*
- *DecSec* (hundredths of a second of the shot time)
- *WaterDepth*
- *Gravity*
- *Magnetics*.

Table **STATIONS** contains basic station information. Data fields are:

- *SurveyNo*
- *StationNo*
- *StationName*
- *Latitude*
- *Longitude*
- *Elevation*

Table **TIMEPICKS** lists travel-times picked from the seismic record sections. Data can be imported from the text files used in the modelling packages, with the added fields of *SurveyNo*, *StationNo* and *TraverseNo*. The other fields are:

- *Distance*
- *ReducedTTime*
- *NormalizingVelocity*

The last two fields are native to the record section used for picking. By convention, distances are negative West of the station for West-East trending lines and negative South of the station for North-South trending lines. The corresponding form gives a filter selecting a particular pick file.

Table **TIMEZONES** contains a list of recorder time zones used in the whole database. There are only two field at present,

- *TimeZone*
- *UTCcorrection* (in hours)

Table ***TRAVERSES*** contains start and end UT dates of traverses. The fields are:

- *SurveyNo*
- *TraverseNo*
- *StartDate*
- *EndDate*

Additional fields may be added here, like shot numbers and locations, which would help to catalogue land shots and dispense with the *SHOTPOS* table.

Some of the forms in *SURVEYS.MDB* are based on queries: *CHOOSEAZIMUTH*, *CHOOSEDISTANCE*, *CHOSERECORDERLINETIMES*, *SHOTDISTCONTENTS* and *TIMEPICKSCONTENTS*. The output of each query is presented in the form view.

*CHOOSEAZIMUTH* prompts the user for a survey number and azimuth range. The query searches table *SHOTDIST* giving minimum and maximum shotpoint numbers for a specific traverse at a specific station satisfying this criterion. *CHOOSEDISTANCE* queries table *SHOTDIST* on distance range, giving output similar to that of *CHOOSEAZIMUTH*.

*CHOSERECORDERLINETIMES* is designed to find out which traverses were recorded by a given station on a given survey. Recorder operating times are converted to Universal Time and compared with line shooting times.

*SHOTDISTCONTENTS* and *TIMEPICKSCONTENTS* are summaries of the data in *SHOTDIST* and *TIMEPICKS* tables. They sort the data into station-line pairs and tell how many of those are found in each table. Minimum and maximum distances and azimuths are also selected for every pair.

## DATABASE USERS

Microsoft Access<sup>®</sup> contains a facility which permits creation of *USER GROUPS* sharing a common database. Members of the same group run Access<sup>®</sup> using the same system files, specifying privileges to each user. There are two system files: *SYSTEM.LDB* and *SYSTEM.MDA*. They should always be placed in the C:\ACCESS\SETUP directory. Currently, spare copies of these reside on the L:\SEISMIC\USER\DATABASE.

To add a new user to the group, do the following:

1. Copy *SYSTEM.LDB* and *SYSTEM.MDA* to your C:\ACCESS\SETUP directory.
2. Click on the *MSAccess Workgroup Administrator* icon, which should be located in your Microsoft Office directory (with other Access<sup>®</sup> icons).
3. The location of the system database file should be on the network I:\ drive, I:\ACCESS\SYSTEM.MDA. Click on the *Join...* button and change the location to C:\ACCESS\SETUP\SYSTEM.MDA.
4. Click *OK* and *Exit* following the successful link.

Every time you run Access<sup>®</sup> from now on, you will be prompted for a password identifying you as a member of the seismic group.

Surveys database has three user groups: *ADMIN*, *USERS* and *GUESTS*. *ADMIN* has all the privileges to the database (ie. can modify table and form structures, as well as add, delete or update data). *USERS* can add, delete and update data in tables only, but they cannot change database design. *GUESTS* can view data only.

At the moment, only three database users exist. They are prompted for their user names every time they try to run Access<sup>®</sup> and *SURVEYS.MDB*. Individual users can set passwords by going into *SECURITY - CHANGE PASSWORD...* menu while in Access<sup>®</sup>. New users can be added by *ADMIN* at a later stage.

Only one *ADMIN* and *GUEST* exist at the moment. *ADMIN* account is protected by a password. Only *ADMIN* can read the database exclusively (ie. not in a shared environment).

## DATABASE INTERFACE

*SURVEYS.MDB* can import data into individual tables from external spreadsheets or text files. Prior to import one has to make sure that the format of these files agrees with the structure of the table (ie. the number of columns is correct and that the data is in the right order). The following example illustrates a typical import to a shot distance table, *SHOTDIST*. The input file is generated by program *DISTANCE* during processing of analog data.

Shot distance files have a \*.PDP extension and contain a one row header (giving information on the station and traverse number, eg. "Stn 16, Line 401 Shot Distance File"), followed by data columns: shot number, distance from the station, shot time, azimuth, water depth. Prior to import into table *SHOTDIST*, one needs to remove the header, shot time and water depth columns. It is easiest done in Excel<sup>®</sup>:

1. Open a file and start import from the second row (that gets rid of the header). Choose Next.
2. Skip the shot time and water depth columns and click on Finish.
3. Data records in table *SHOTDIST* are identified by a survey, station and traverse numbers. Add these three columns in front of shot number, distance and azimuth.
4. Duplicate the entries for the rest of the spreadsheet.
5. Save the file in an Excel<sup>®</sup> format.
6. Open the surveys database and click on the import button - .
7. Select data source (Microsoft Excel 5.0) and the file name, click on Import.
8. In Table Options, choose Append to Existing Table and select *SHOTDIST*.
9. Click on OK.

Once the import is finalised, status message will be given (number of records added and number of potential import errors). *IMPORT ERRORS* table will give the row numbers and fields (from the original Excel<sup>®</sup> file) with problems. These can be cross-checked and corrected later (errors may occur due to incorrect data formats (eg. ascii characters in number fields, etc.)). Access<sup>®</sup> will not import a given field for a particular record if errors are detected ie. if there are problems with the azimuth field, it will remain blank (null) for a given shotpoint. One can select records with null fields by running an Access<sup>®</sup> query and typing the correct values at a later stage. Once all the errors are fixed, the *IMPORT ERRORS* table can be deleted from the database. Note the import procedure can be cancelled if an excessive number of errors occurs.

## **APPENDIX 4**

### **WIDE-ANGLE SEISMIC PROFILING DATABASE: ARCHIVAL STRUCTURE FOR OTWAY BASIN 1994/95 PHASE I REFRACTION SURVEY**

**DIRECTORY PATH:** L:\SEISMIC\OTWAY137

**REPORT.DOC:** Operational Report for the Otway Basin 1994/95 Refraction Survey (Finlayson and others, 1995)

**OTWAY137.XLS:** Spreadsheet containing basic survey parameters, eg. station positions and operating times, traverse information, analog recorder clock drifts. Both phases of the survey (December 1995 and January 1996 are covered).

**STATUS.XLS:** Spreadsheet containing current status of analog to digital conversion of December 1995 refraction data.

**FLOWCHTS.XLS:** Spreadsheet showing processing stream used for the Otway 1995 data (includes the names of Fortran programs and examples of generated files).

All the digitised shot data reside in the **ARCHIVE** directory.

## **STATION NUMBERS, NAMES AND ABBREVIATIONS**

**STATION NO. STATION NAME STATION ABBREVIATION**

1	Milltown	mi
2	Gorae	go
3	Riddles Road	rr
4	Red Lane 1	la
6	Ewen Hill	ew

Data Sets are grouped in Station-Traverse Subdirectories, eg. digitised files from Station 1 are located in mi\*\*\* subdirectory, where \*\*\* is the Traverse Number. Shotpoint files are stored in a compressed form (\*.zip file(s), eg. mi500.zip for Station 1, Line 500). Upon decompression, the files are grouped in subdirectories containing approx. 2,000 shots at a time (A, B, C, etc.). These files have been corrected for the station clock drift by program TRUETIM3. The original PDP11 files are kept in PDP11 Subdirectory, all in one compressed file (eg. mi500raw.zip for Station 1, Line 500). Zipped file includes data in original PDP11 format as well as PC reformatted version (character "n" in second letter of the file prefix). Drifts Subdirectory contains list of shot file names used by TRUETIM3 for clock corrections. Additional Subdirectory Cfcorr contains a list of the old tape speed correction factors from the shot headers (which have been averaged to improve record section plots).

It is noted here that most of the archived files are NOT corrected for the variable playback tape speed (sampling interval). CORRFAC must therefore be run on the cracked files prior to plotting (existence of Cfcorr subdirectory means that the archived data has been corrected). Also, due to error in reading the GPS clock on board of "Rig Seismic", 903ms must be SUBTRACTED from the shot times in the headers (alternatively, 903ms must be ADDED to the picks after processing). Corrected picks are stored in the MODEL directory (additional "c" is added to the pick file name).

BATHYM directory contains plots of water depth along the specific traverses and original ascii data from "Rig Seismic" for all the lines.

GRAVITY directory stores scanned images of the gravity field in the offshore Otway Basin.

PLOTS directory contains seismic record sections in the \*.TIFF format (used for publication purposes).

SHOTS directory contains original "Rig Seismic" files giving positions and Julian Day times of the shots (note the earlier mentioned 903ms problem).

STATIONS directory contains station position file (STATIONS.POS) and clock drift file for the recorders (Drifts subdirectory). Individual station subdirectories contain PDP11 distance files and Excel<sup>®</sup> files containing shot files corrected for local time (e.g. daylight saving) and for errors due to incorrect dip-switch settings on the Omega radio time signal receivers.

## **APPENDIX 5**

### **WIDE-ANGLE SEISMIC PROFILING DATABASE: ARCHIVAL STRUCTURE FOR BROWSE BASIN 1993 REFRACTION SURVEY**

**DIRECTORY PATH:** L:\SEISMIC\NWSHELF\BRWSE119

**REPORT.DOC:** Operational Report for the Browse Basin 1993 Refraction Survey (Collins and others, 1995).

**STATUS.XLS:** Spreadsheet containing current status of analog to digital conversion of June 1993 refraction data.

**FLOWCHTS.XLS:** Spreadsheet showing processing stream used for the Browse 1993 data (includes the names of Fortran programs and examples of generated files).

All the digitised shot data resides in the **ARCHIVE** directory.

## **STATION NUMBERS, NAMES AND ABBREVIATIONS**

STATION NO	STATION NAME	STATION ABBREVIATION
------------	--------------	----------------------

1	Browse Is	br
2	Bigge Is	bi
3	Lamarck Is	la
4	Mitchell Plateau	mp
5	Cape Leveque	cl

Data Sets are grouped in Station-Traversal Subdirectories, eg. digitised files from Station 1 are located in br\*\*\* subdirectory, where \*\*\* is the Traversal Number. Shotpoint files are stored in a compressed form (\*.zip file, eg. br1001.zip for Station 1, Line 1001). These files are stored in an uncracked form i.e. in large multi-shot files (as opposed to Otway Basin Phase I December 1993 survey).

These files have been corrected for the station clock drift by program NEWTIME. The original PDP11 files are kept in PDP11 Subdirectory, all in one compressed file (eg. br1001raw.zip for Station 1, Line 1001). Zipped file includes data in original PDP11 format. Drifts Subdirectory contains a list of shot file names used by NEWTIME for clock corrections. Subdirectory Cfcorr contains a list of the old tape speed correction factors from the shot headers (which have been averaged to improve record section plots).

Record section time picks are stored in the MODEL directory.

BATHYM directory contains plots of water depth along the specific traverses.

SHOTS directory contains a zipped file SHOTS.ZIP with original "Rig Seismic" files giving positions and Julian Day times of the shots (all lines) and merged shot files for individual traverses (used by program DISTANCE).

STATIONS directory contains station position file (STATIONS.POS). ShipClok subdirectory contains drift files for the GED clock used on board of "Rig Seismic". Individual station subdirectories contain PDP11 distance files and station drift files in Drift subdirectory. Net station

clock error has been interpolated using ship clock errors and analog recorder clock errors, final files have the format NETERR\*\*.TXT, where \*\* is the station number. Spreadsheets contain drift plots for the recorder clocks.
