FOREWORD

This is the third in a series of reports prepared by the Bureau of Mineral Resources, Geology & Geophysics (BMR) to present data on Australian petroleum accumulations. Each report provides information about the characteristics of the petroleum found so far in a particular sedimentary basin, and presents the data together with notes on the geographic and geologic setting, stratigraphy, structure, traps, reservoir and source rocks, reserves and any production developments. The reports are designed to provide a ready reference to those interested in petroleum exploration and development in Australia.

This report summarises the data from the 50 petroleum accumulations found to date in the Gippsland Basin. Other reports published to date cover the Amadeus and Bass Basins. Reports on the Adavale, Bonaparte, Otway, Surat, Bowen, Eromanga and Cooper basins are scheduled for publication within the next two years.

ABSTRACT

The Gippsland Basin in southeastern Victoria, is Australia's major crude oil and natural gas producing province. To the end of 1986 the basin had supplied 88 per cent of Australia's cumulative crude oil production and 48 per cent of cumulative natural gas production. Crude oil and natural gas were first discovered onshore in 1924, near Lakes Entrance, Victoria. Since then over 125 onshore wells have been drilled, resulting in the discovery of one (1) subeconomic and six (6) uneconomic petroleum accumulations. More than 80 exploration and step-out wells have been drilled offshore, resulting in the discovery of eleven (11) economic, twenty-six (26) subeconomic and six (6) uneconomic petroleum accumulations.

The petroleum in the Gippsland Basin mainly occupies structural and structural/stratigraphic traps within the Oligocene, Eocene, Paleocene and Late Cretaceous marine, marginal marine and continental clastic sequences. The petroleum is believed to be of land-plant origin; crude oil results from thermal breakdown of exinite, and natural gas from thermal cracking of vitrinite and exinite.

The crude oils are generally very light and paraffinic, ranging from 40 to 60^{O}API. Some heavier oils discovered at shallow depths range from 14.6 to 26.5^{O}API and are thought to have been biologically degraded. The condensates range from 48 to 63^{O}API. The natural gases are generally low in condensate content. Some gas reservoirs contain a high proportion of carbon dioxide.

Production of natural gas and oil commenced in 1969 and 1970 respectively. Cumulative production to 31 December 1986 was 344.66 x $10^{6}m^{3}$ of oil, 9.68 x $10^{6}m^{3}$ of condensate, 41.75 x $10^{6}m^{3}$ of LPG and 66.14 x $10^{9}m^{3}$ of sales gas. The oil and gas produced is transported from the twelve offshore production facilities (platforms) by pipeline to gas and crude oil stabilisation plant at Longford, Victoria for processing, and then to storage and distribution centres.

Estimated remaining recoverable petroleum reserves in the Gippsland Basin as at 31 December 1986 are 202.44 x $10^{6}m^{3}$ of oil, 22.44 x $10^{6}m^{3}$ of condensate, 44.89 x $10^{6}m^{3}$ of liquid petroleum gas, and 206.39 x $10^{9}m^{3}$ of sales gas.

INTRODUCTION

This report summarises information on the petroleum accumulations found in the Gippsland Basin up to 30 June 1987 (Fig. 1). It describes the basin setting, structure and traps, reservoir and source rocks, nature of petroleum, and petroleum reserves and developments.

The objectives of the report are:

- to provide an overview of the distribution and character of petroleum accumulations in the Gippsland Basin;
- to provide information likely to assist in exploration for additional reserves, and in
- basic geological, and geochemical research.

Data presented in this report were drawn from various sources including the results of petroleum exploration and development programs in the Gippsland Basin and assessments of individual accumulations released by operating companies.

BASIN SUMMARY

Setting and stratigraphy

The Gippsland Basin is a Late Mesozoic/Tertiary basin located mainly offshore in the northeastern part of Bass Strait between the mainland of Australia and Tasmania, underlying an area of some 63 000 km^2 to the 200 m bathymetric contour (Fig. 2). The northern boundary is an unconformable contact between basin sediments and rocks of the Tasman Fold Belt, and the northwestern boundary with the Otway Basin is the Selwyn Fault on Mornington Peninsula. The eastern boundary is undefined, but basin sediments extend beyond the shelf break, near the 200 m bathymetric contour. The Gippsland Basin is separated from the Bass Basin to the southwest by a southeast-trending basement ridge, the Bassian Rise.

The stratigraphy of the Gippsland Basin is shown in Figure 3 and in Plates 1 to 7 inclusive, and has been described in varying detail by Boutakoff (1964); James and Evans (1971); Hocking (1972); Threlfall and others (1976); Robertson and others (1978) and Brown (1987). The stratigraphic succession has been interpreted, in plate-tectonic terms, to represent the interplay of Cretaceous and Tertiary events leading to the opening of the Tasman Sea and Southern Ocean, and the development of the southeastern and southern continental margins. Geological cross-sections showing the relationship of main rock units of the Gippsland Basin are given in Figure 4.

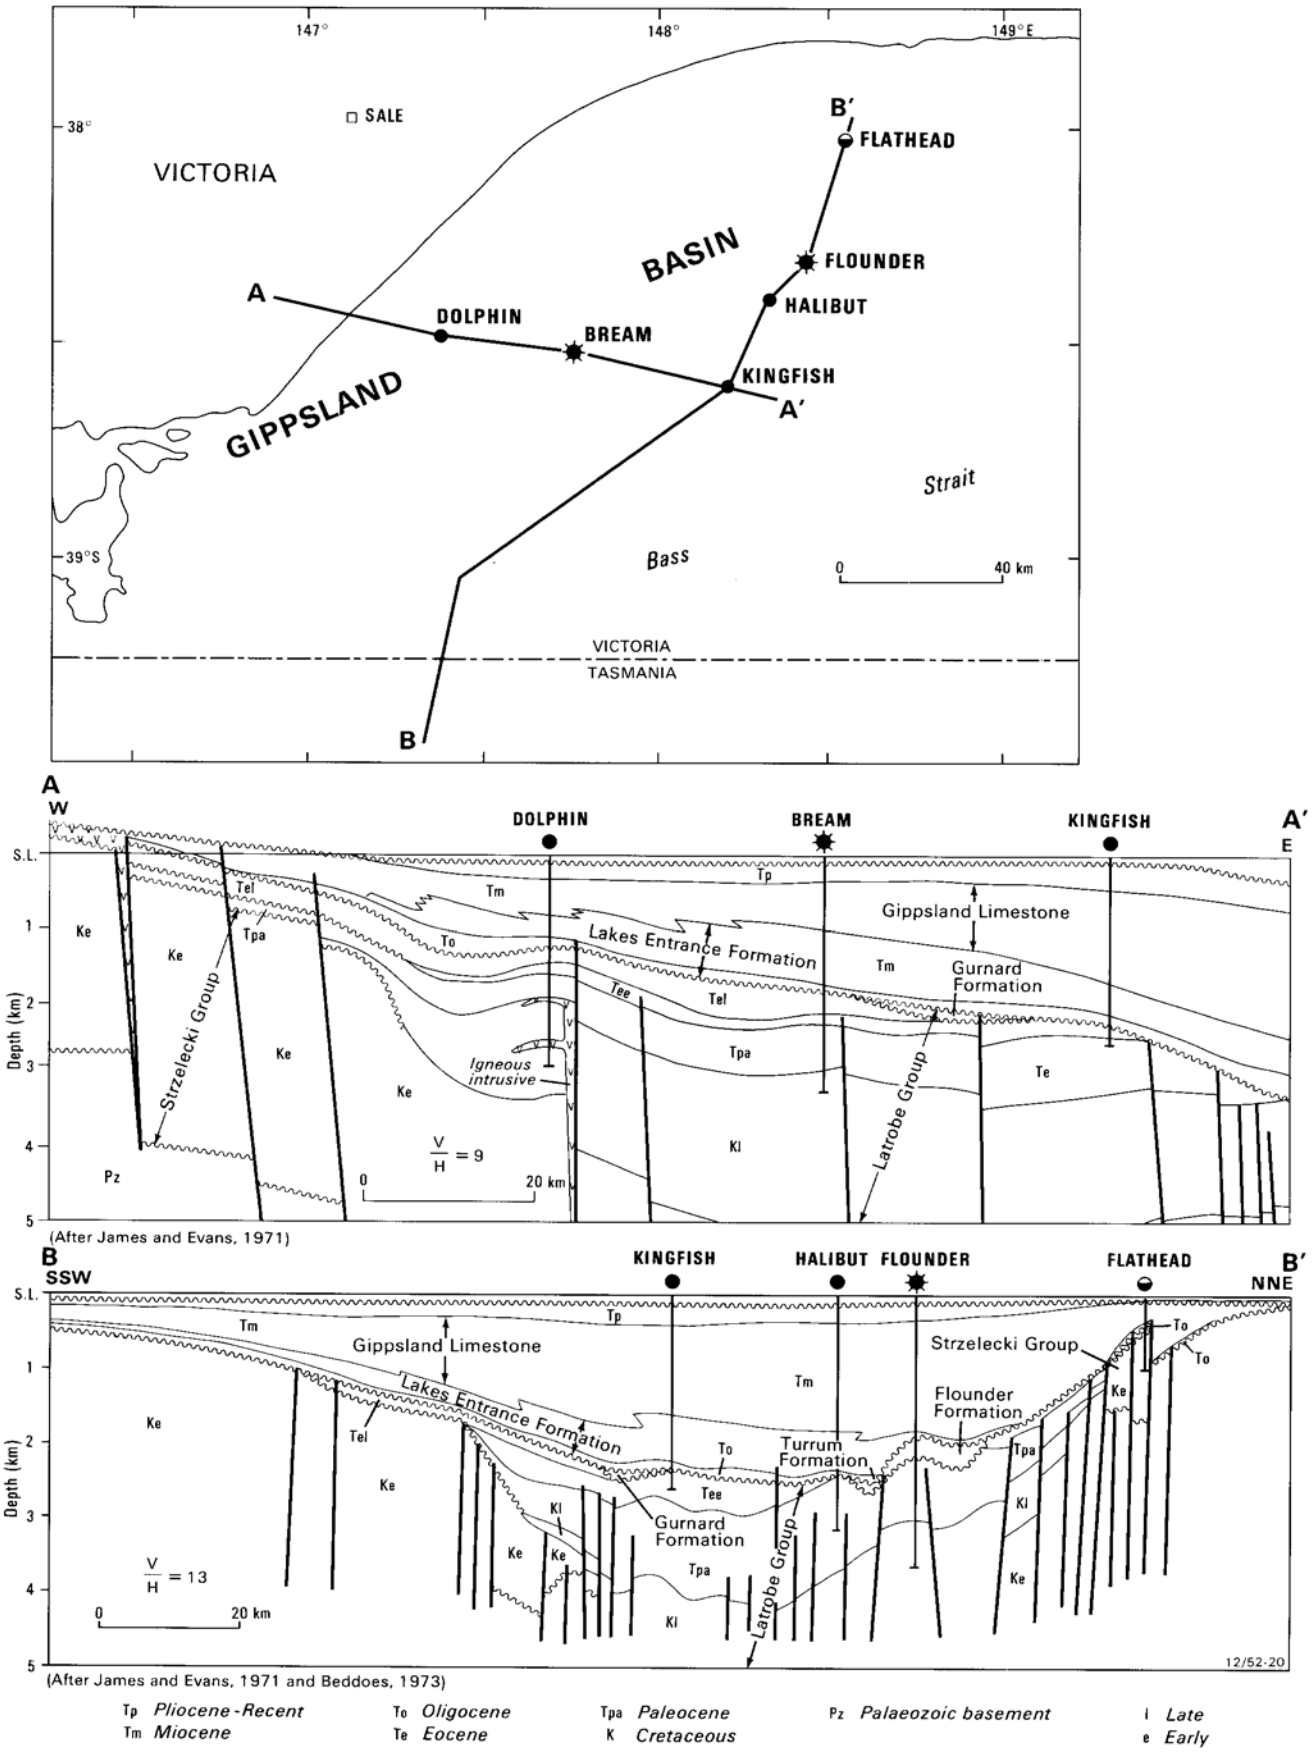

Fig. 4 Stratigraphic and structural relationship of main rock units, Gippsland Basin

The Early Cretaceous (? and Late Jurassic) Strzelecki Group occurs in a central north-west trending graben. Where intersected, near the margins of the graben, the sediments are continental, and the relationship with the overlying sequence, unconformable. Late Cretaceous graben-fill continental sediments in the lower part of the overlying Latrobe Group are overlain by a Late Cretaceous to Eocene sequence deposited during the northwesterly marine transgression of the basin which followed the onset of continental break-up. The latter sequence comprises fluvio-deltaic sediments, with marginal marine deposits preserved along the migrating shoreline. A widespread diachronous unconformity at the top of the sequence has been attributed by Partridge, (1976) to the non-preservation of sediments seaward of the marginal marine environment. The Tuna-Flounder and Marlin sub-marine channel systems, dissect the top of the Latrobe Group and reflect erosional episodes associated with structural movements in the Early and Late Eocene respectively.

The Oligocene to Recent section is a southeasterly prograding continental shelf sequence which exhibits a gradual change in the Miocene, from shale and marl of the Lakes Entrance Formation to marl and limestone comprising the Gippsland Limestone. Onshore continental deposition was continuous in the Latrobe Valley region and in southeastern Gippsland continental deposition returned following a marine regression in the Pliocene.

Petroleum accumulations

The offshore Gippsland Basin is Australia's major crude oil and natural gas producing province. Oil and gas were first discovered in 1924 by Lake Bunga No. 1 (Fig. 5) a water well near Lakes Entrance, Victoria (Robertson and others, 1978). Since then over 125 onshore wells have been drilled resulting in discovery of 1 subeconomic and 5 uneconomic accumulations. Over 80 exploration and step-out wells have been drilled offshore resulting in the discovery of 11 economic; 26 subeconomic and 6 uneconomic accumulations. The definitions of economic status of all discoveries are given in the Glossary (Page 252).

Economic accumulations

- Barracouta, oil and gas
- Marlin, oil and gas
- Kingfish, oil
- Fortescue, oil
- Halibut, oil
- Cobia, oil
- Mackerel, oil
- Flounder, oil and gas
- Snapper, oil and gas
- Tuna, oil and gas
- Bream, oil and gas

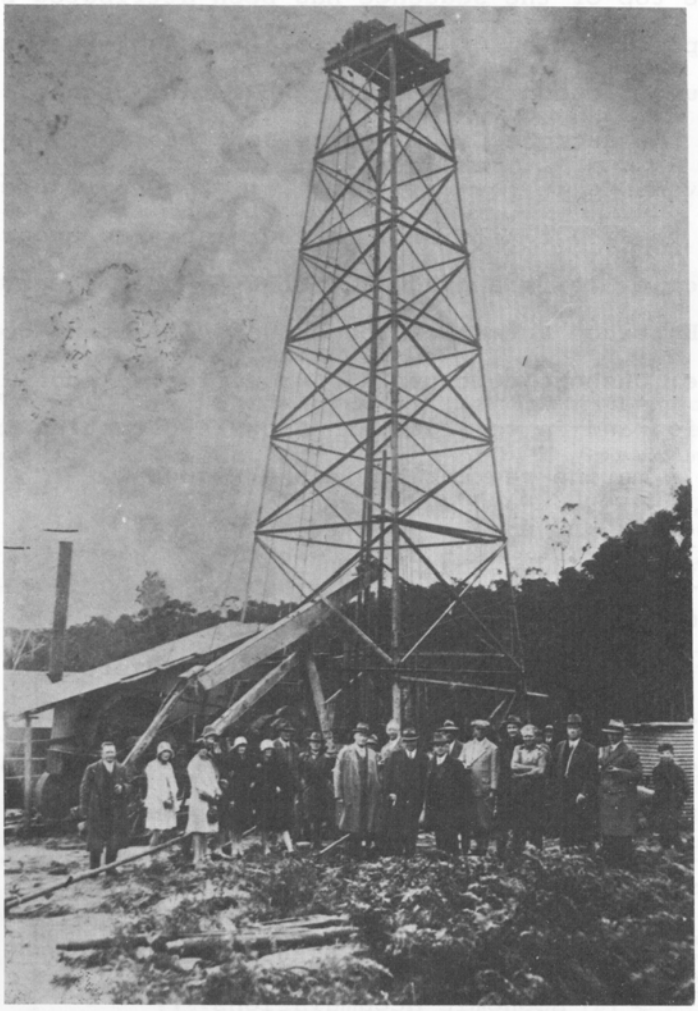

Fig. 5 Lake Bunga No. 1 in 1924 at Lakes Entrance, Victoria (By courtesy of Department of Industry, Technology and Resources, Victoria)

Subeconomic accumulations

- Batfish, gas
- Dolphin, oil
- Emperor, oil and gas
- Golden Beach, gas
- Grunter, oil and gas
- Hapuku, oil
- Kipper, gas and oil
- Seahorse, oil
- Sunfish, oil and gas
- Tarwhine, oil and gas
- West Seahorse, oil and gas
- Whiptail, oil
- Sperm Whale, oil
- Wirrah, oil and gas
- Yellowtail, oil
- Angelfish, oil and gas
- Baleen, gas
- Basker, oil and gas
- Flathead, oil and gas
- Lakes Entrance, oil
- Leatherjacket, oil and gas
- Luderick, oil and gas
- Manta, oil and gas
- Omeo, gas/condensate
- Perch, oil
- Sole, gas
- Whiting, oil and gas

Uneconomic accumulations

- Bignose, gas
- Hermes, gas
- North Seaspray, gas
- Pelican Point, oil and gas
- Selene, gas
- Stonefish, oil and gas
- Sunday Island, oil
- Veilfin, gas
- Volador, oil and gas
- Wellington Park, oil
- Woodside 1, oil and gas
- Woodside 2, oil and gas

Details of all the basin's accumulations are given in the 'Petroleum accumulations summaries' section of this report, and illustrated in Plates 1 to 7.

Nomenclature of traps and petroleum-bearing units

Plates 1 to 7 depict the geological age of the trap(s) and the stratigraphic position of individual petroleum-bearing units in each accumulation. The petroleum-bearing units are identified by a letter code based on the spore pollen-assemblages recognised in the Cretaceous to Oligocene sequence (Fig. 6), and numbered according to the downward order of occurrence within the assemblage. In the case of the Fortescue accumulation, which occurs in the same spore-pollen assemblage as the underlying Halibut-Cobia accumulations, the prefix 'F' is added to the unit identifications (Fig. 7).

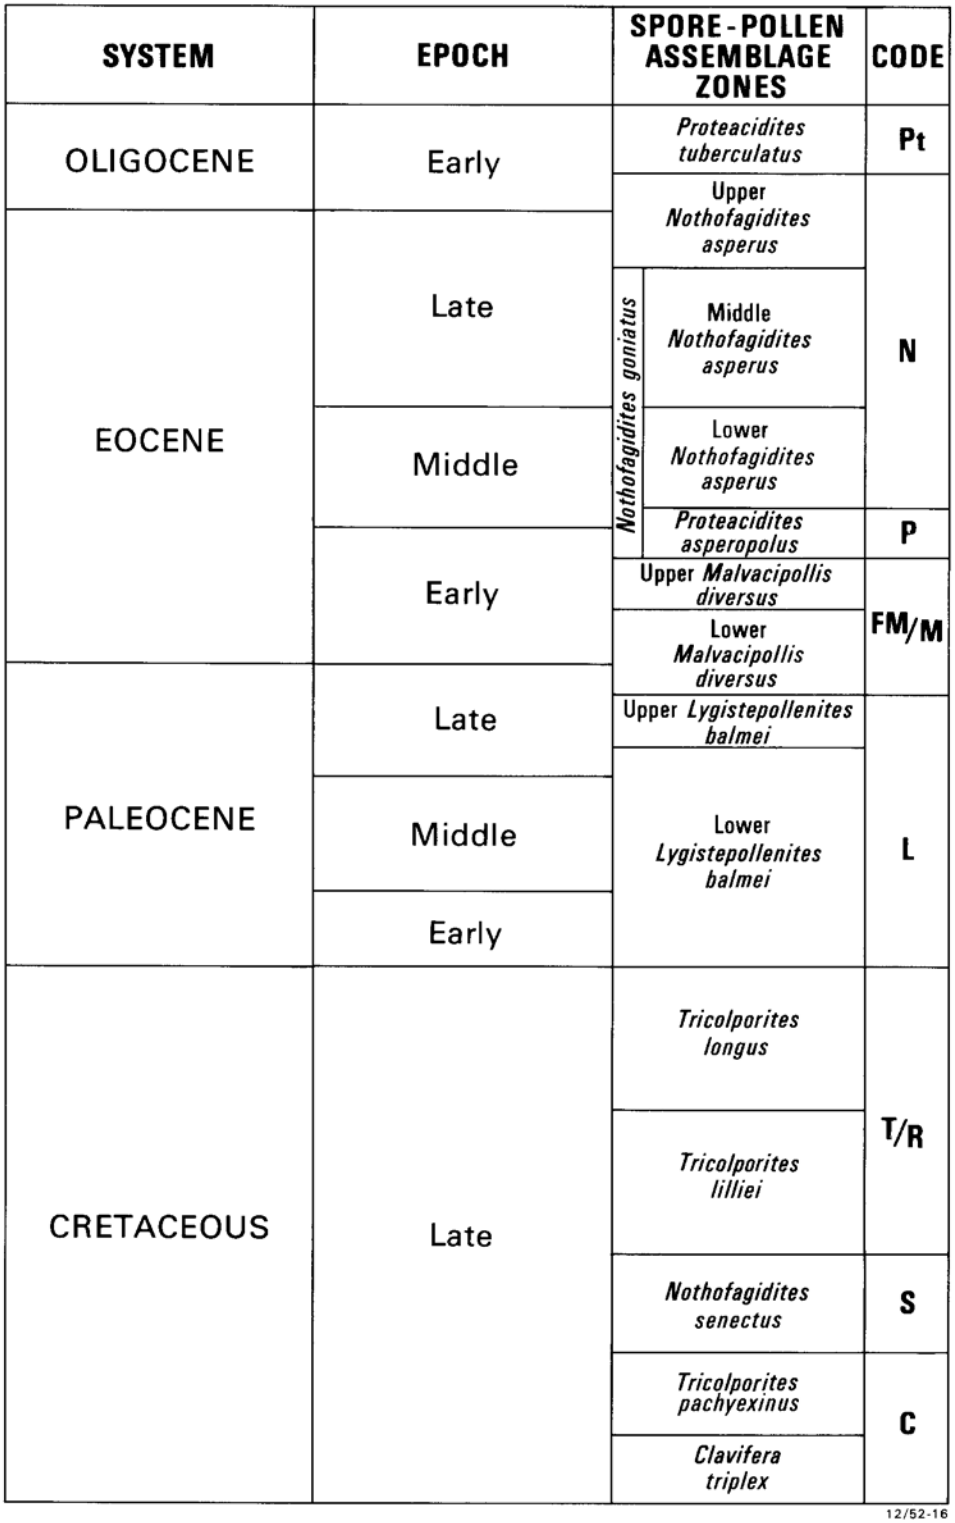

Fig. 6 Spore-pollen zonation, Gippsland Basin

(After Partridge, 1976)

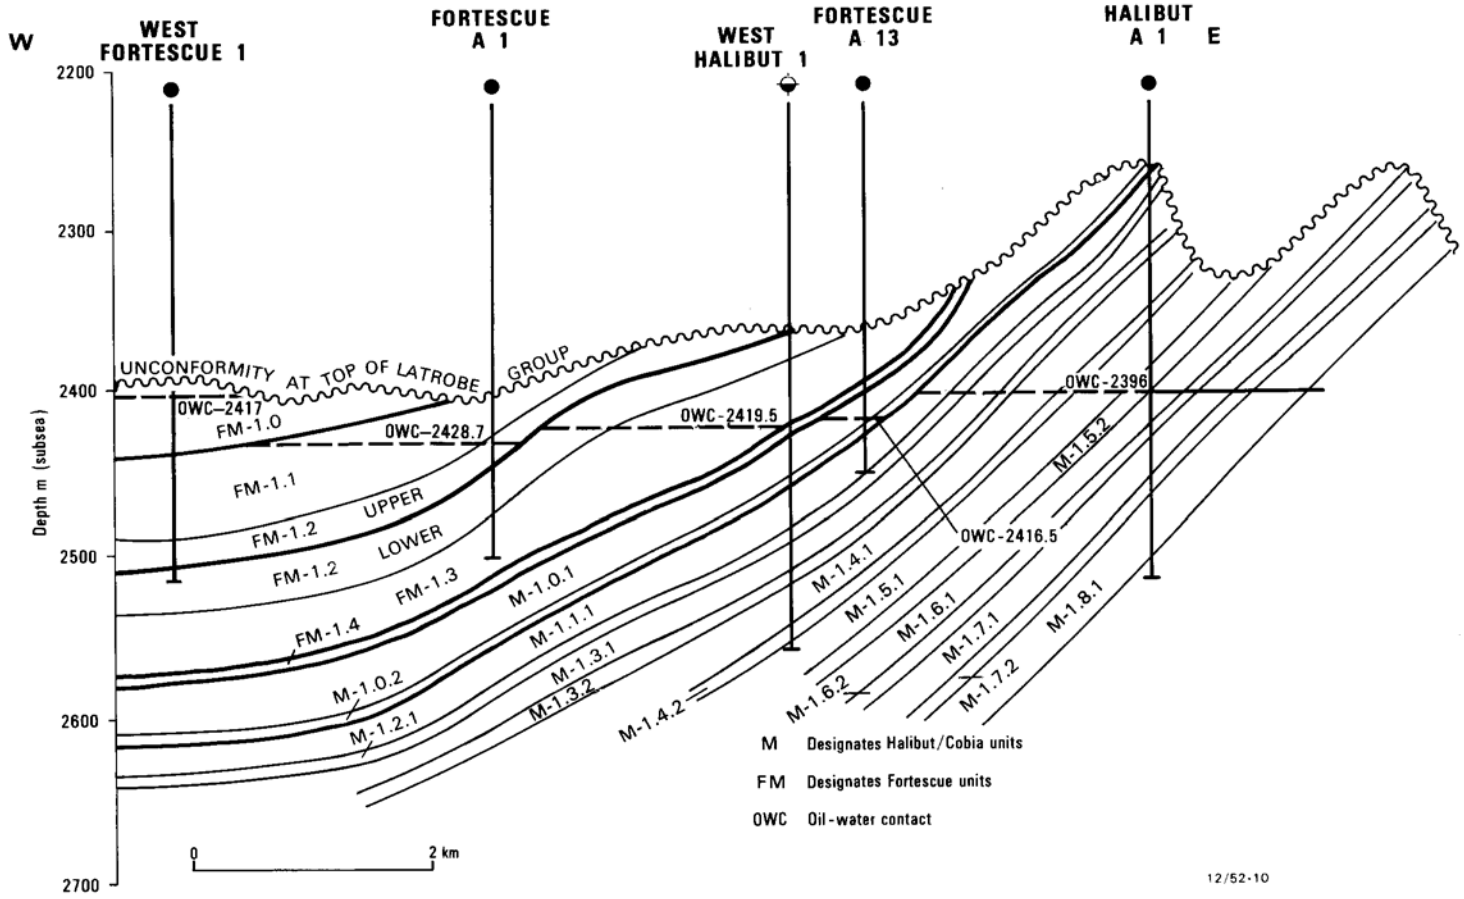

Fig. 7 Structural cross-section. Fortescue-Halibut-Cobia accumulations

(After Henzell and others, 1985)

Structure and traps

Two main structural elements are recognised in the Gippsland Basin; northwest-trending normal fault structures developed during a tensional tectonic regime operative from the Early Cretaceous (? and Late Jurassic) to the Early Eocene (Fig. 8), and the northeasterly to easterly-trending anticlines and associated wrench faults, developed under a compressional tectonic regime in the Late Eocene (Fig. 9). In addition, recent work by the Bureau of Mineral Resources, using BMR 1982 and company seismic data has identified major Early Cretaceous structural lineaments which traverse the basin at right-angles to the trend of the normal fault system. The lineament features have been interpreted by Etheridge & others (1985) as transfer faults which are analogous to oceanic transform faults. Reactivation of the transfer faults, and of the northwest-trending normal faults, is postulated to have been a major controlling factor in the development of the younger compressional structure (Etheridge and others, 1985).

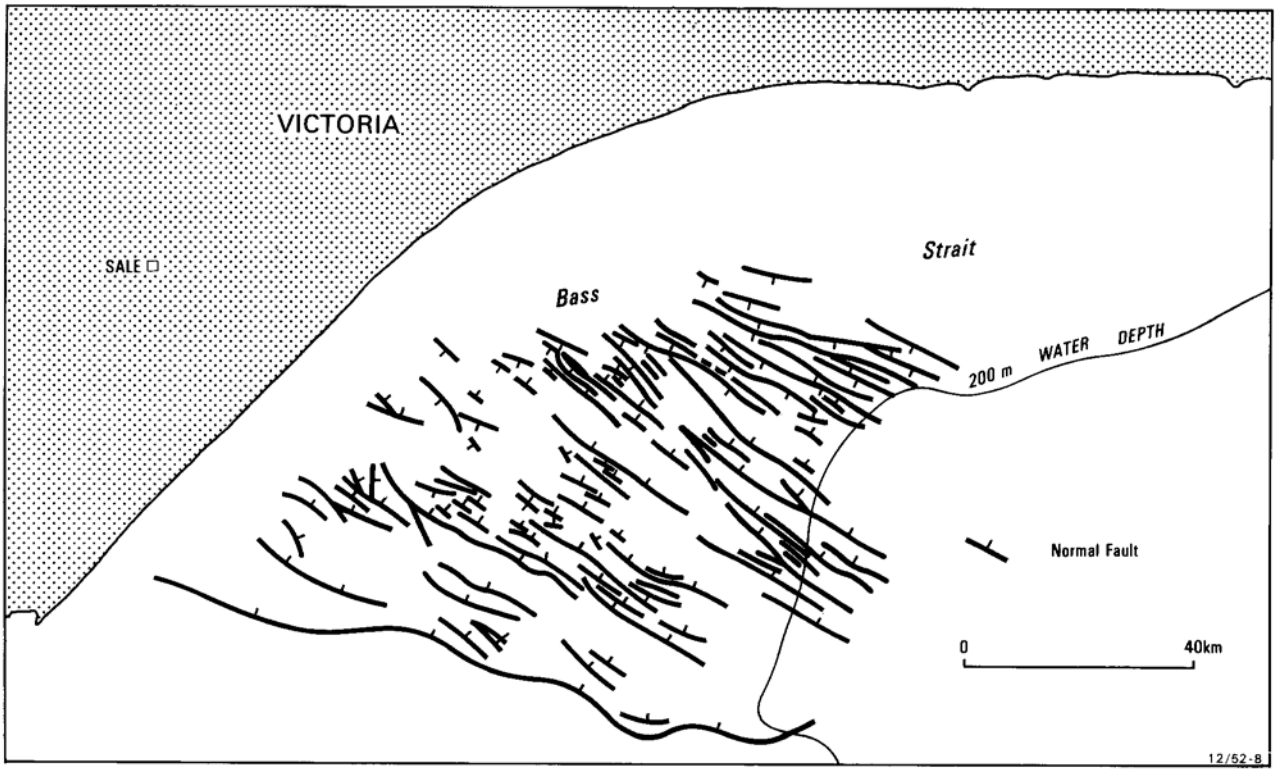

Figure 8. Early Cretaceous to Paleocene basin-forming normal faults, Gippsland Basin (after Threlfall & others, 1976; Ozimic & others, 1987)

The largest petroleum accumulations in the Gippsland Basin are present in the central part of the basin (Fig. 10; Plates 1, 2 & 3) immediately below the unconformity at the top of the Latrobe Group, in traps located along the axes of major anticlinal axes (Fig. 9). The traps are primarily structural, or structural/stratigraphic in origin, with vertical seal provided by the overlying marine shale and marl. Migration of oil to the top of the Latrobe Group was facilitated by a westerly regional dip of the sequence from the basin centre, and vertical pathways provided by normal faults. Petroleum is also trapped in sandstone reservoirs sealed by (intra-formationally) shale within the Latrobe Group. The trapping mechanism is either stratigraphic, resulting from pinchout of the reservoir sands, or structural, where sands are sealed across fault planes by the shale units.

In the Lakes Entrance accumulation, the only significant onshore discovery, oil is trapped stratigraphically within a glauconitic sandstone unit (Greensand Member) of the Oligocene Lakes Entrance Formation.

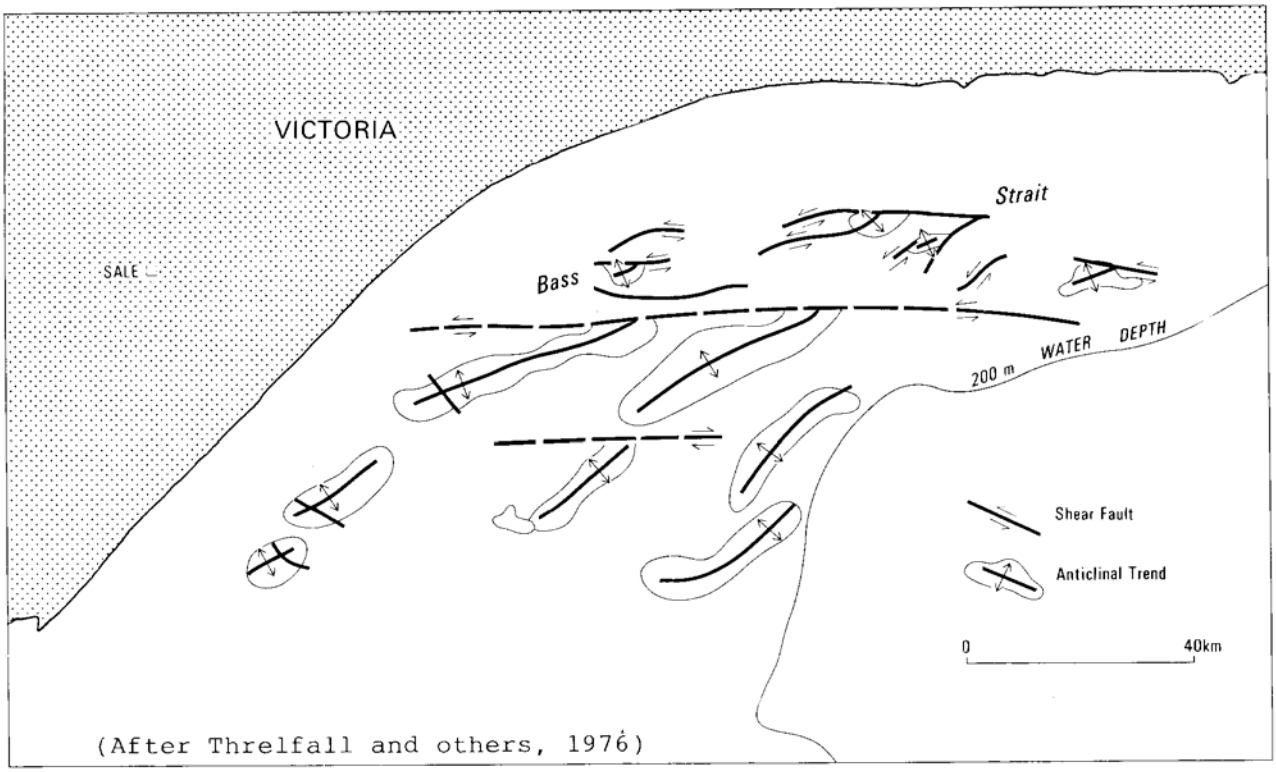

Fig. 9 Late Eocene-Early Oligocene and Late Miocene anticlines and shear faults, Gippsland Basin

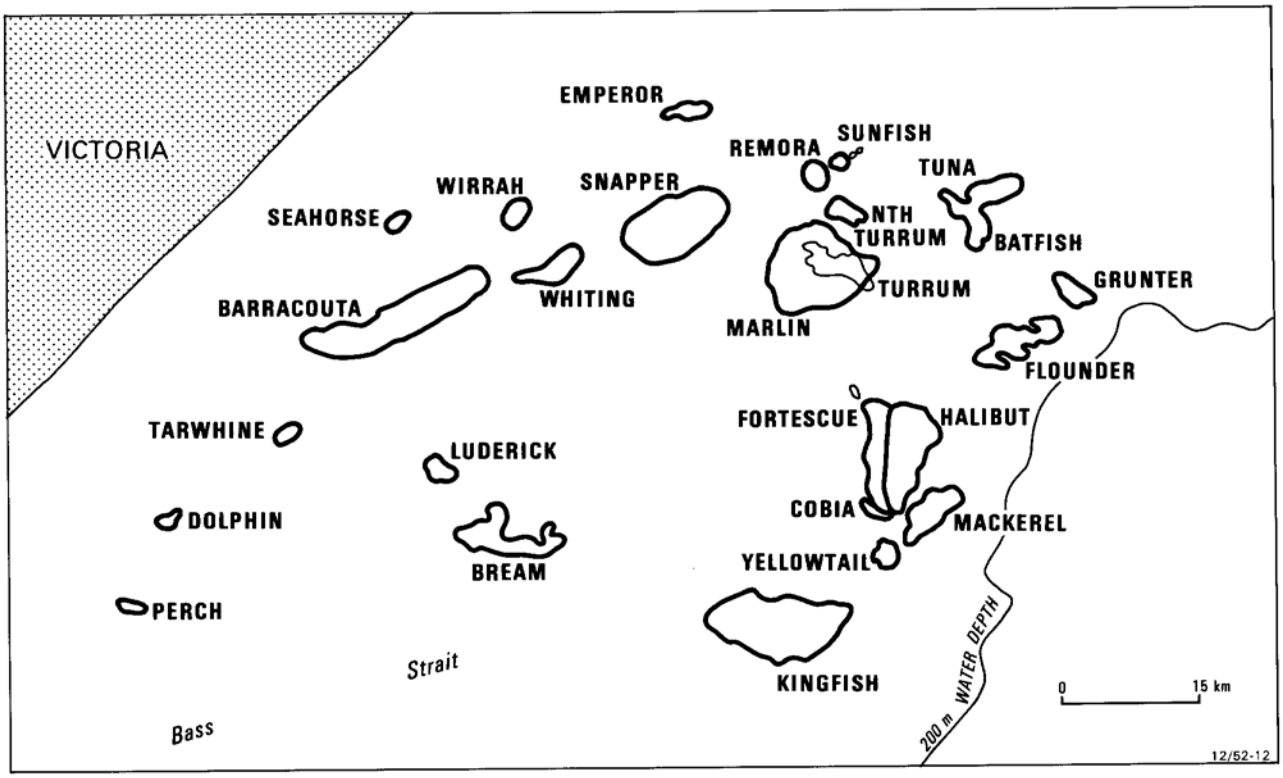

Fig. 10 Location of major petroleum accumulations, Gippsland Basin

Reservoir rocks

Latrobe Group reservoirs comprise four major lithofacies, including: alluvial valley; progradational coastal plain; coastal barrier, and near-shore marine. The Eocene Top Latrobe Group reservoirs which host most of the major petroleum accumulations comprise friable to unconsolidated sands with minor scattered zones of dolomitisation. The porosity of these reservoirs ranges from 15 to 30 per cent while permeabilities are frequently in excess of 1 Darcy. The Paleocene and Late Cretaceous intra-Latrobe Group reservoirs are somewhat compacted and porosity readings in these units ranges form 5 to 15 per cent with permeability of up to 1000 md.

Cap rocks to the Latrobe Group petroleum-bearing units are impervious sandstone, siltstone, shale, marl and coal.

The Lakes Entrance Formation contains a single petroleum-bearing unit, the Greensand Member which hosts the heavy tarry oil (15.7°API) of the Lakes Entrance accumulation (Plate 5). The quality of the Greensand Member reservoir is poor.

Source rocks and maturation

Geochemical work of Brooks and Smith (1969) and chromatographic analysis of crude oils from the Gippsland Basin (Powell and McKirdy, 1976; Shibaoka and others, 1978) suggest a terrestrial organic origin for the Gippsland Basin oil and gas.

Three distinct organic matter assemblages, or facies have been identified by Smith and Cook (1984). Two of these, Cretaceous to Early Eocene, and Middle and Late Eocene ages were first recognised in the Lower and Upper Eastern View coal measures of the Bass Basin and are named accordingly. The third, the Latrobe Valley facies, is recognised in the Latrobe Valley onshore and in nearshore areas of the Gippsland Basin. The distribution, type and abundance of organic matter in each of these three facies are shown in Table 1. The main hydrocarbon source is believed to be that part of the sequence currently at depths of 4 km. The oil being attributed to thermal breakdown of exinite, and gas to thermal cracking of vitrinite and some exinite.

The isoreflectance contours (R_V max per cent) estimated by Smith and Cook are shown in Figure 11, and a plot of vitrinite reflectance against depth in Figure 12. The data indicated an overall increase of reflectance values with depth, a decrease in reflectance gradient from the basin margin into the Central Deep, and an increase in gradient with depth.

Smith and Cook (1984) suggest that much of the oil in the Gippsland Basin is generated at a low coal rank (R_V max 0.4-0.8 per cent), from vitrinite and exinite which occurs at burial depths between 2 and 4 km. Stainforth (1984) in his evaluation of Gippsland Basin hydrocarbons has shown however that a R_V max 0.7 per cent maturity level is required for significant oil generation in these terrestrial plant source rocks. On the other hand there is direct chemical evidence for oil generation at approximately R_V max 1.0 per cent maturity level (Pers. comm. Dr T. Powell, BMR) and which is supported by gas isotope data from Burns and others, (1984).

Petroleum types

Oils and condensates found within the Gippsland Basin are paraffinic to napthenic in composition, they have a high wax content, and are characterised by high pristane to phytane ratios (Powell and McKirdy, 1976). A typical gas chromatograph signature of Gippsland Basin oils is illustrated in Figure 13. High wax content and high pristane to phytane

TABLE 1 - SUMMARY OF MAJOR CHARACTERISTICS OF OTHER ORGANIC MATTER FACIES IN THE GIPPSLAND BASIN (After Smith and Cook, 1984)

Facies		Lower Eastern View		Upper Eastern View	Latrobe Valley
		A	B

ratios (greater than 5) are indicative of a terrestrial plant source. A feature in line with the conclusions reached by Brooks (1970), Saxby (1980), Burns and others (1984), and Smith and Cook (1984).

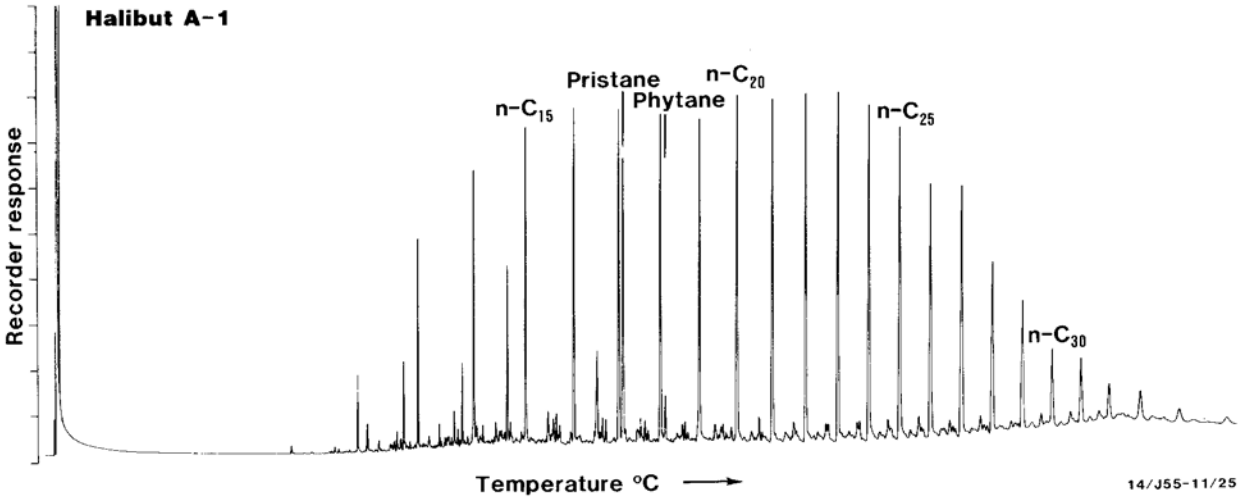

Fig. 13 Gas chromatograph of the saturated hydrocarbons obtained from the Halibut accumulation

The Gippsland Basin oils are generally light (Fig. 14) and have API gravities, ranging from 40 to 60°. Some heavier oils, discovered at shallow depths, have gravities of 14.6 to 26.5°API, and are thought to have been biologically degraded. Other properties of selected Gippsland Basin crude oils are given in Table 2. The gravity of Gippsland condensates range from 48 to 63°API.

In general, oils from terrestrial sources are classified as high wax oils (Hedberg, 1968) although a wide range of compositions can occur. In the Gippsland Basin some oils have condensate-like compositions with API gravities of 50°API or more, no wax content, and virtually no compounds heavier than about C_{22}. Other Gippsland oils have an API gravity of 35°, are extremely waxy and are made up of molecules heavier than C_{20}. In between these two extremes are many combinations and variations in such properties. Burns and others (1987) suggest that such compositional variations can be explained by the oils having been generated at different

TABLE 2 - CRUDE OIL PROPERTIES FROM SELECTED GIPPSLAND BASIN ACCUMULATIONS

Accumulation	Lakes Entrance	Barracouta*	Halibut*	Kingfish*	Hapuku*

maturity levels, and possibly by separation migration. Bacterial degradation, which ranges from mild to severe, has introduced additional complexity and had varying effects on quality, depending on the initial oil composition.

The composition of natural gases recovered in the Gippsland Basin varies slightly but most accumulations have low condensate yields (less than 30 bbl/million scft). High carbon dioxide contents are observed in some cases. Analytical data on natural gases recovered from selected Gippsland Basin accumulations are listed in Table 3 and reflect the type and range of composition.

Non-petroleum gases

A number of gaseous and liquid petroleum accumulations discovered in the Gippsland Basin contain varying concentrations of carbon dioxide, hydrogen sulphide, nitrogen and helium (Table 4). Such non-petroleum gases

are significant potential by-products of petroleum production as they may result in equipment failure through corrosion or an environmental hazard.

The carbon dioxide is of organic origin (Stainforth, 1984). The origin of hydrogen sulphide and nitrogen have not been investigated.

The helium is undoubtedly related to some radioactive elements or isotopes in shales or granite basement underlying the basin.

Reserves and production

The Gippsland Basin is the most prolific petroleum producing basin in Australia. The estimated remaining recoverable petroleum reserves as at 31 December 1986 comprised 202.44 x 10^6m^3 of oil; 67.33 x 10^6m^3 of natural-gas liquids; and 206.39 x 10^6m^3 of sales gas (BMR, 1987). The commercial and non-commercial recoverable reserves as at 31 December 1986 are listed in Table 5. Cumulative production up to 31 December 1986 was 344.66 x 10^6m^3 of oil; 51.43 x 10^6m^3 of natural-gas liquids; and 66.14 x 10^9m^3 of sales gas (BMR, 1987).

Assessment of the basin's commercial plus non-commercial recoverable oil and sales gas reserve assessments from 1965 to 1986 is shown in Figure 15. On the same figure, cumulative oil and sales gas production is also shown.

TABLE 5 GIPPSLAND BASIN COMMERCIAL AND NON-COMMERCIAL RECOVERABLE RESERVES (AS AT 31 DECEMBER 1986)

	COMMERCIAL	NON-COMMERCIAL
Oil (10^6m^3)	172.77	29.67
Condensate (10^6m^3)	21.03	1.41
LPG (10^6m^3)	48.89	-
Sales Gas (10^9m^3)	164.56	41.84

Developments

Natural gas production commenced from the Barracouta accumulation in 1969, and oil production from the Halibut accumulation in 1970.

The first group of platforms: Barracouta, Marlin, Halibut and Kingfish A and B, were built at the Barry Beach marine terminal, 193 km southeast of Melbourne, and installed in Bass Strait between mid 1967 and late 1969. A second group; Mackerel, Tuna, Cobia, Snapper, Fortescue, West Kingfish, and Flounder were installed between 1976 and 1985.

There are currently 12 production platforms (Table 6) and each has a current capacity of between 10 and 27 wells per platform. Production

TABLE 6 GIPPSLAND BASIN DEVELOPED PETROLEUM ACCUMULATIONS

Accumulation (Platform)	Locality map number (Plate 1-2)	Accumulation type	Distance from shore	Water depth	Number of well slots	Date production started
Barracouta	1	Gas & Oil	24.1 km	46 m	10	March 1969
Marlin	2	Gas & Oil	52.5 km	58.5 m	24	January 1970
Kingfish A	3	Oil	75.6 km	77.1 m	21	April 1971
Kingfish B	3	Oil	77.2 km	77.7 m	21	November 1971
West Kingfish	3	Oil		76.0 m	27	December 1982
Fortescue	4	Oil	65.0 km	69.0 m	21	May 1983 from Cobia platform
Halibut	5	Oil	64.4 km	72.5 m	21	March 1970
Cobia	6	Oil	66.0 km	78.0 m	21	April 1983
Mackerel	7	Oil	72.4 km	92.7 m	18	December 1977
Flounder	8	Oil & Gas	58.9 km	93.0 m	27	December 1984
Snapper	9	Gas & Oil	32.0 km	54.9 m	27	July 1981
Tuna	10	Oil & Gas	56.3 km	58.5 m	18	May 1979
Bream	11	Oil & Gas	under development		27	---

equipment on each platform separates and measures produced petroleum liquids, gas and water before they are transported by pipeline to gas processing and crude stabilisation plants at Longford. Each platform is also equipped with pumping and compression facilities. Most producing wells are equipped with dual, tandem or single completions, depending on the reservoir drainage requirements.

Development of the Bream accumulation commenced in 1987 with construction of a 27-conductor platform. Additional developments are planned for currently producing fields and undeveloped discoveries but the timing of these developments depends on economic conditions.

Production systems in the Gippsland Basin are depicted in Plates 1 to 7 (Petroleum Production System) and in Figure 16. Stabilisation at the Longford plant involves the separation of lighter hydrocarbons (methane, ethane, propane and butane) from the crude oil. The stabilised crude oil is piped over 188 km to a crude oil tank farm at Long Island Point, on Westernport Bay, where it awaits transport by tanker or pipeline to petroleum refineries. Gas from the offshore fields and light hydrocarbons

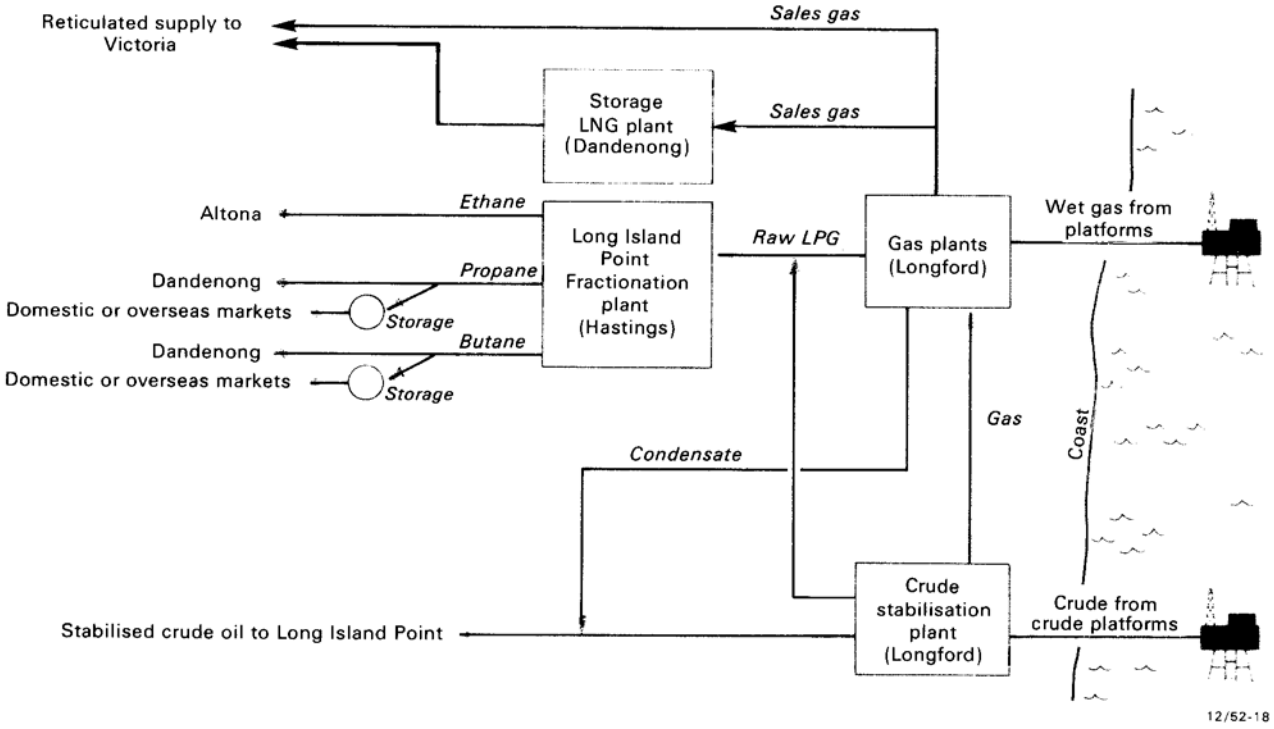

Fig. 16 Schematic of crude oil and natural gas production system in the Gippsland Basin

(By courtesy of Esso Australia Ltd and BHP Petroleum Pty Ltd)

produced by the crude stabilisation process are fed into the three gas plants where methane (and some oil) is separated. The remaining hydrocarbons are piped to Dandenong for storage and distribution. Product recovered from gas processing and crude stabilisation which comprises a mixture of ethane, propane and butane is liquified (by pressurising to 6895 Kp) and piped to the Long Island Fractionation Plant for final separation. Liquified petroleum gas (LPG) is stored offshore in the Barracouta M-1 petroleum-bearing unit and onshore in refrigerated tanks. Ethane is piped to a petrochemical plant at Altona where it is used as chemical feedstock. Petroleum carrying pipelines in the Gippsland Basin are listed in Table 7.

Sales gas and LPG storage

Considerable parts of the natural gas recovered from the Gippsland Basin fields are stored in underground and surface installations.

Some sales gas from the Longford gas plant is piped to Dandenong where it is liquified and stored (Fig. 16). The Dandenong liquid natural gas (LNG) plant was brought into service in 1980 which provides a back-up supply for the Gas & Fuel Corporation. The back-up supply increases capacity and improves the security of reticulated supply to urban, regional and industrial users in Victoria. The plant has a storage tank capacity of 12 000 tonnes of LNG or the equivalent of 20 x $10^6 m^3$ of natural gas (Burt, 1986).

In the offshore Gippsland Basin Esso/BHP are using the Barracouta partially depleted oil-bearing unit of the Barracouta accumulation to store liquified petroleum gas (LPG). This storage was developed in 1971 to avoid cutbacks to crude oil and natural gas production, due to limited onshore storage problems and maintenance shut-downs at the Long Island Point fractionation plant. Excess raw LPG from the onshore facilities is piped to the Barracouta platform and injected into the M-1 petroleum-bearing unit (Fig. 17, Plate 1). Since 1971, 420 000 m^3 of LPG have been injected of which 220 000 m^3 have been produced (Williams, 1986). The injected LPG has also acted as a gas miscible displacement mechanism in the reservoir and has improved oil recovery beyond that possible by primary methods.

TABLE 7 GIPPSLAND BASIN PETROLEUM PIPELINES

Pipeline	Length	Nominal diameter	Service
Barracouta to Longford			
Offshore	24.5 km	450 mm	Gas
Onshore	24.5 km	450 mm	Gas
Barracouta to Longford			
Offshore	23.6 km	150 mm	Oil/LPG
Onshore	30.6 km	150 mm	Oil/LPG

PETROLEUM ACCUMULATIONS SUMMARIES

NOTES ON DEVELOPMENTS

BARRACOUTA: the beginning of Australia's offshore petroleum exploration and development . . . .

On a December dawn in 1964, off Gippsland's lonely Ninety Mile Beach, the drilling ship Glomar III broke sea bottom 46 metres below surface to spud in Australia's first offshore wildcat well.

The well Esso Gippsland Shelf No. 1 (later renamed Barracouta No. 1) discovered natural gas in February 1965. A second, or stepout, well was drilled in June and confirmed that gas existed in the Barracouta accumulation in commercial quantities.

Esso Gippsland Shelf No. 1 well was the first well drilled under an agreement reached in 1964 between Hematite Petroleum Pty Ltd, a BHP subsidiary, and Esso Exploration and Production Inc.

In December 1965 the Victorian Government reacted quickly to the Gippsland gas discovery and created a Ministry of Fuel and Power to control the development and use of Victoria's energy resources.

In April 1967, a Petroleum Production Licence was issued to Esso/BHP under the joint Commonwealth-State legislation to develop the Barracouta accumulation.

Gas production commenced in March 1969.

PETROLEUM ACCUMULATIONS SUMMARY SHEET

ACCUMULATION: *Barracouta*

COMPILATION DATE: *02/03/87*

OPERATOR: *Esso Australia Ltd*

TYPE: *Gas and oil*

COMMERCIAL STATUS: *Economic and developed*

LOCATION: *Approximately 249 km east of Melbourne; and 51 km southeast of Lakes Entrance, offshore Victoria*

STATE: *Victoria*

PETROLEUM TITLE(S): *Vic/P1, Vic/L1, Vic/L2*

FIRST DISCOVERY WELL: *Esso Gippsland Shelf No.1 (Esso, 1965)*
- latitude: *38º16'41"* - longitude: *147º42'45"*
- discovery: *gas*
- date total depth reached: *May 1965*

SECOND DISCOVERY WELL: *Barracouta A-3 (Esso, 1968)*
- latitude: *38º17'53"* - longitude: *147º40'29"*
- discovery: *oil; gas-oil; gas*
- date total depth reached: *July 1968*

THIRD DISCOVERY WELL: *Barracouta A-7 (Esso, 1968)*
- latitude: *38º17'53"* - longitude: *147º40'29"*
- discovery: *oil*
- date total depth reached: *November 1968*

FOURTH DISCOVERY WELL: *Barracouta No.5 (Esso, 1985)*
- latitude: *38º18'04"* - longitude: *147º39'36"*
- discovery: *oil*
- date total depth reached: *February 1985*

NUMBER OF WELLS DRILLED: *5* exploration
10 development

STRUCTURE: *Anticline: northeast-southwest trending; divided by a traverse fault (Structure map, Plate 1)*
- areal closure: > *50 sq.km*
- vertical closure: > *180 m*

SUBDIVISION OF PETROLEUM ACCUMULATION:
5 traps
8 petroleum-bearing units

NUMBER AND TYPE OF PRODUCING ZONES:

Nil	gas	*1*	gas/condensate
Nil	gas/oil	*1*	oil

DRIVE MECHANISM: *Water drive*

PRODUCTION COMMENCED: *March 1969: gas (N-1)*
October 1969: oil (M-1)

From January 1971 to March 1974 the N-4 unit produced some 206,000 barrels of oil via Barracouta A-7 well. During the same period about 800 barrels of oil was also produced from the N-5 unit via Barracouta A-7 well.

The M-1 oil producing sand has been used for storage of liquid petroleum gas (LPG) since December 1971; LPG is injected into the M-1 unit at least twice a year and is produced as required.

PRODUCTION INFRASTRUCTURE: *Ten well platform in 46 m of water; connected via 49 km and 54.2 km long oil and gas pipelines to gas processing and crude oil stabilisation plant at Longford, Victoria*

NOTES ON DEVELOPMENTS

MARLIN: the gas blowout . . . . . .

On 2 December 1968 a gas blowout occurred on the Marlin production platform while the drilling of the Marlin A-7 development well was in progress.

Gas from a sand within the Eocene blew out and erupted from the seabed near the platform without igniting.

After delays caused by bad weather the blowout was brought under control on 1 January 1969.

Full scale gas production commenced in November 1969.

Drilling from the platform was not resumed until 12 June 1972.

NOTES ON DEVELOPMENTS

KINGFISH: a giant oil accumulation, 1000 million barrels plus . . . . . .

Up to April 1967 a commercial crude oil discovery had eluded the Gippsland Basin explorers.

This changed when during that month the drillship Glomar III spudded in the Kingfish No. 1 well, 77.2 km offshore, in water 78 metres deep.

In June of that year Esso/BHP declared that the Kingfish discovery was commercial, with initial recoverable reserves of 1000 million barrels plus, still the largest known oil accumulation in Australia.

By world standards the Kingfish discovery ranks among the giant oil accumulations. This discovery thrust Australia from almost total dependence on overseas oil supplies to one of near self-sufficiency.

Production from the Kingfish accumulation commenced in January 1971. Its production infrastructure comprises 3 platforms: Kingfish 'A', Kingfish 'B' and West Kingfish.

NOTES ON DEVELOPMENTS

FORTESCUE: 'old' oil – 'new' oil . . . . . .

When in September 1978 the West Halibut No. 1 well encountered oil-bearing rocks at a depth below the original oil-water contact of the adjacent Halibut accumulation, it appeared that a separate oil accumulation may have been discovered. This discovery was subsequently designated the Fortescue accumulation.

The Fortescue discovery is interpreted as a separate oil accumulation discrete from the adjacent Halibut accumulation on the basis of a lower oil-water contact and a significant pressure differential across a rock unit separating the two accumulations.

The price of crude oil produced in Australia has been subject to government control since major production commenced in 1964. In September 1975, the then Prime Minister announced a policy which meant that, for the first time, there would be substantially different prices paid for oil from different accumulations.

Under the policy, oil from newly discovered accumulations was to be differentiated from oil produced from accumulations already discovered. 'New' oil was to attract a price at the nearest refinery port equivalent to the landed cost of imported crude (Import Parity Price) minus a levy.

The key elements in the definition of 'new' oil are:

1. *'New' oil means any crude oil, not including natural gas liquids or condensate, discovered after 17 September 1975.*

2. *Any such discovery shall be a naturally occurring discrete accumulation.*

The Fortescue oil discovery satisfied all the above key elements, and it therefore qualified as 'new' oil under the Commonwealth Government's crude oil pricing policy.

Production from the Fortescue accumulation commenced in May 1983 via the adjacent Cobia platform and in September 1983 via the Fortescue platform.

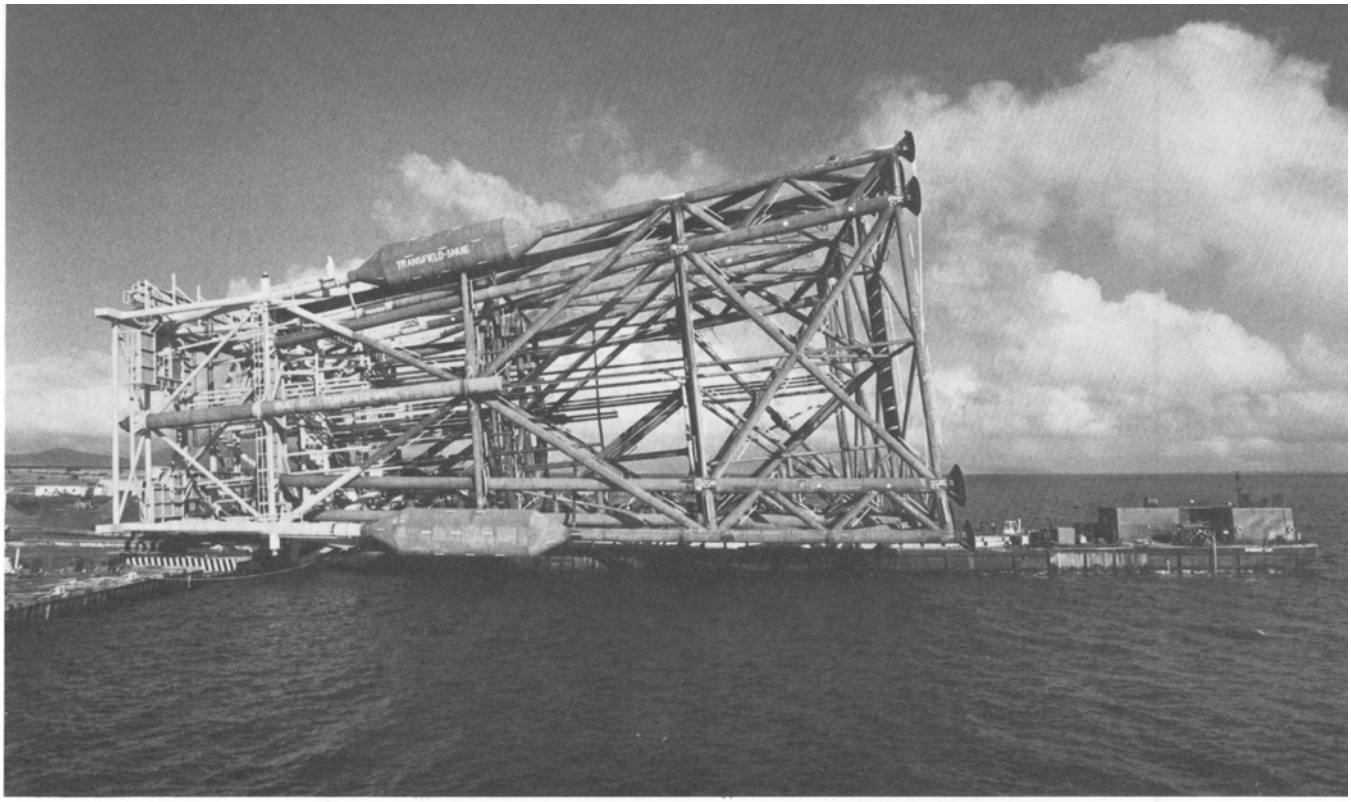

Fig. 20 Bream platform jacket at Barry Beach, Victoria
(By courtesy of Esso Australia Ltd and BHP Petroleum Pty Ltd)

NOTES ON DEVELOPMENTS

HALIBUT: a large petroleum production platform . . . .

Large platforms, like Halibut, are taller than a 25 storey building and on their sides are longer than a football field.

The Halibut 24 well capacity platform was erected early in 1968 about 78 km offshore, in water 72.5 metres deep. A total of 21 wells were drilled, of which 19 became oil producers. Production commenced in March 1970.

Barry Beach, a marine terminal in Victoria, is where the jackets of Gippsland Basin production platforms are built. After the onshore construction, the jackets are floated out into Bass Strait from Barry Beach on a barge. They are then positioned and completed as production platforms.

NOTES ON DEVELOPMENTS

COBIA No. 2: a subsea production system – the first of its type for Australia . . . . . .

Prior to 1979, discoveries of petroleum in the Gippsland Basin were developed exclusively by the use of conventional platforms. Cobia No. 2, the first subsea production system in Australia, was brought on stream on June 30, 1979.

The subsea production system comprised five significant elements: downhole equipment; Christmas tree; flowlines; platform facilities; and control system.

The Cobia No. 2 Christmas tree was located in water 73 metres deep and was connected to the Mackerel platform by a flowline 4.4 km long.

The Cobia No. 2 subsea production system was dismantled after completion of the Cobia production platform in April 1983.

All the Bass Strait platforms have special safety measures. In the unlikely event of an escape of gas or a fire, the wells would be shut off, water or chemical foam would automatically cover the platform to kill the fire, horns would blare, and lights would flash. These safety measures mean most emergencies can be quickly brought under control. If the workers do have to leave the platform they report to their safety escape capsule, called a Brucker. Bruckers can travel over the sea even if there is burning oil on the water. They are stocked with emergency equipment and food.

NOTES ON DEVELOPMENTS

MACKEREL No. A-14: a very high angle well . . . . . .

In the early 1970s the location of Bass Strait production platforms was determined by using a 45% to 50% angle of deviation limit for directional wells.

This limit was gradually extended with each platform until a very significant change was achieved with the Mackerel No. A-14 well drilled with an average deviation angle of 69%.

The history of Mackerel No. A-14 begin in 1973 when the Mackerel No. 4 exploration well was drilled with the objective of evaluating the Mackerel southern fault block. While the well encountered a significant oil column, there was much uncertainty as to the true geological structure of the fault block. It is believed that either minimum or no communication exists between the oil trapped by the fault block and the oil contained in the main Mackerel field being drained by the Mackerel A platform.

Feasibility studies indicated that the most economical methods of producing this oil was either through a subsea completion, similar to Cobia No. 2, or through a very high angle well drilled from the Mackerel A platform.

The Mackerel No. A-14 well achieved a combination of extremely high angle (69%), together with deep true vertical depth of approximately 2400 metres by drilling 5200 metres of directional hole.

Production from the well commenced in November 1979.

NOTES ON DEVELOPMENTS

FLOUNDER: an abnormal pressure zone . . . . . .

In August 1968 drilling on the Flounder prospect had to be suspended when high pressure fluids were encountered.

In order to control the high pressure, drill-muds up to 30 percent heavier than normal were used. Despite this, wireline logging of the well was not possible.

As a result, the operator suspended drilling because equipment in use was not considered adequate for safety, and the rig was moved to another prospect.

Drilling of the Flounder prospect resumed in March 1969. Since then over 22 wells have been drilled, resulting in delineation of another major oil and gas accumulation in the Gippsland Basin.

Production of oil from Flounder commenced in December 1984.

NOTES ON DEVELOPMENTS

SNAPPER: the development of 'pancake' type oil column . . . . . .

Oil columns of 2 to 15 metres overlying aquifers and underlying a large gas cap are generally referred to as 'pancake' type oil columns. These are common in Gippsland Basin accumulations.

Following the construction and placement of the Snapper platform in 1981, it was recognised by the operator that full gas deliverability was not required initially as the Marlin and Barracouta accumulations could meet existing demand. This situation enabled the Snapper development wells to be drilled with the initial objective of developing the thin 'pancake' oil column underlying the large gas cap.

Several high angle wells were required for oil production which presented drilling and logging problems. However, 16 of the 21 wells drilled succeeded in intersecting oil zones suitable for production. Subsequent performance of the oil wells was encouraging.

Snapper, the first development of a 'pancake' oil column in the Gippsland Basin, has provided valuable and encouraging experience in the well completions and surface equipment required for this type of operation.

Production of oil and gas commenced in July 1981.

NOTES ON DEVELOPMENTS

TUNA: what's in a name . . . .

In the offshore Gippsland Basin there are over forty petroleum accumulations that are named after species of fish. The Tuna accumulation bears a name of one of these (Thunnus albacares).

After a platform is placed in Bass Strait it soon becomes covered with marine organisms such as seaweed, shellfish etc. Seals can be seen sunning themselves on the mooring buoys or swimming around the platform jackets.

In order to keep the plants, birds, fish and seals safe, the platform operators have safety equipment on the platform so as to make certain that the surrounding environment is protected from environmental hazards.

PETROLEUM ACCUMULATIONS SUMMARY SHEET

ACCUMULATION: *Tuna*

COMPILATION DATE: *23/03/87*

OPERATOR: *Esso Australia Ltd*

TYPE: *Gas and oil*

COMMERCIAL STATUS: *Economic and developed*

LOCATION: *Approximately 42 km offshore Victoria; and 19 km northeast of marlin accumulation*

STATE: *Victoria*

PETROLEUM TITLE(S): *Vic/L4, Vic/L9*

FIRST DISCOVERY WELL: *Tuna No.1 (Esso, 1968)*
- latitude: *38º10'25"* - longitude: *148º25'03"*
- discovery: *oil and gas*
- date total depth reached: *October 1968*

SECOND DISCOVERY WELL: *Tuna No.3 (Esso, 1970)*
- latitude: *38º10'10"* - longitude: *148º26'50"*
- discovery: *oil and gas*
- date total depth reached: *April 1970*

THIRD DISCOVERY WELL: *Tuna A-5 (Esso, 1979)*
- latitude: *38º10'16"* - longitude: *148º25'06"*
- discovery: *oil and gas*
- date total depth reached: *December 1978*

FOURTH DISCOVERY WELL: *Tuna A-8 (Esso, 1979)*
- latitude: *38º10'16"* - longitude: *148º25'07"*
- discovery: *oil*
- date total depth reached: *February 1979*

FIFTH DISCOVERY WELL: *Tuna A-7 (Esso, 1979)*
- latitude: *38º10'16"* - longitude: *148º25'06"*
- discovery: *oil*
- date total depth reached: *October 1979*

SIXTH DISCOVERY WELL: *Tuna A-17 (Esso, 1981)*
- latitude: *38º10'16"* - longitude: *148º25'06"*
- discovery: *oil*
- date total depth reached: *September 1980*

SEVENTH DISCOVERY WELL: *Tuna A-6 (Esso, 1981)*
- latitude: *38º10'16"* - longitude: *148º25'60"*
- discovery: *oil*
- date total depth reached: *November 1981*

EIGHTH DISCOVERY WELL: *Tuna No.4 (Esso, 1984)*
- latitude: *38º10'16"* - longitude: *148º25'06"*
- discovery: *oil and gas*
- date total depth reached: *July 1984*

NUMBER OF WELLS DRILLED: *4* exploration
18 development

STRUCTURE: *Anticline: east-northeast trending; truncated along the northern flank; faulted along the southern flank by northwest-southeast trending faults (Structure map, Plate 3)*
- areal closure: > *7 sq.km*
- vertical closure: > *80 m*

SUBDIVISION OF PETROLEUM ACCUMULATION:
6 traps
17 petroleum-bearing units

PETROLEUM CONTENTS: *Oil*
PRODUCTION STATUS: *Nil*
FORMATION: *Lakes Entrance Formation*
AGE: *Oligocene (P.tuberculatus)*
TRAPPING MECHANISM: *Structural*
LITHOLOGY: *Sandstone: marine; unconsolidated; glauconitic; interbedded with glauconitic and calcareous siltstone*
DEPTH TO TOP OF PETROLEUM-BEARING UNIT : *438.0 m BSL*
POROSITY: *Up to 35%*
PERMEABILITY*: Not available*
TEMPERATURE GRADIENT: *Not available*
PRESSURE GRADIENT: *Not available*

TRAP

TRAP 2: *Eocene/Paleocene (M/L)*

DISCOVERY WELL(S): *Flathead No.1*

CONTENTS: *Oil*

PETROLEUM-BEARING UNIT(S)

PETROLEUM-BEARING UNIT 1: *M/L*

PETROLEUM CONTENTS: *Oil*
PRODUCTION STATUS: *Dormant*
FORMATION: *Latrobe Group*
AGE: *Eocene/Paleocene (M.diversus/L.balmei)*
TRAPPING MECHANISM: *Structural*
LITHOLOGY: *Sandstone: non-marine; unconsolidated*
DEPTH TO TOP OF PETROLEUM-BEARING UNIT : *460.0 m BSL*
POROSITY: *Up to 36%*
PERMEABILITY*: Up to 1200 md*
TEMPERATURE GRADIENT: *Not available*
PRESSURE GRADIENT: *Not available*

TRAP

TRAP 3: *Early Cretaceous (Strzelecki Group)*

DISCOVERY WELL(S): *Flathead No.1*

CONTENTS: *Oil*

PETROLEUM-BEARING UNIT(S)

PETROLEUM-BEARING UNIT 1: *Strzelecki Gp*

PETROLEUM CONTENTS: *Oil*
PRODUCTION STATUS: *Dormant*
FORMATION: *Strzelecki Group*
AGE: *Early Cretaceous*
TRAPPING MECHANISM: *Structural*
LITHOLOGY: *Sandstone: non-marine; carbonaceous and silty; interbedded with carbonaceous siltstone and minor coal*
DEPTH TO TOP OF PETROLEUM-BEARING UNIT : *467.3 m BSL*
POROSITY: *Up to 37%*
PERMEABILITY*: > 500 md*
TEMPERATURE GRADIENT: *Not available*
PRESSURE GRADIENT: *Not available*

PETROLEUM ACCUMULATIONS SUMMARY SHEET

ACCUMULATION: *Lakes Entrance*

COMPILATION DATE: *17/03/87*

OPERATOR: *Woodside (Lakes Entrance) Oil Co.*

TYPE: *Oil*

COMMERCIAL STATUS: *Subeconomic and suspended*

LOCATION: *Approximately 298 km east of Melbourne; and less than 2 km north of Lakes Entrance township, Victoria*

STATE: *Victoria*

PETROLEUM TITLE(S): *Vic/P44*

DISCOVERY WELL: *Lake Bunga No.1 (Beddoes, 1973)*
- latitude: *37°51'22"* - longitude: *148°02'24"*
- discovery: *oil*
- date total depth reached: *July 1924*

NUMBER OF WELLS DRILLED: *1* exploration
54 development

STRUCTURE: *Stratigraphic trap; basal sandy facies of the Lakes Entrance Formation is draped over a southward-plunging paleotopographic nose (Beddoes, 1973)*
- areal closure: *12.9 sq.km*
- vertical closure: *Not determined*

SUBDIVISION OF PETROLEUM ACCUMULATION:
1 traps
1 petroleum-bearing units

NUMBER AND TYPE OF PRODUCING ZONES:

Nil gas	*Nil* gas/condensate
Nil gas/oil	*Nil* oil

DRIVE MECHANISM: *None*

PRODUCTION COMMENCED: *1930*

PRODUCTION INFRASTRUCTURE: *Between 1930 and 1941 some 487 kls of heavy oil (15.7°API) was produced by pumping and bailing (no flow). This scheme was abandoned by the Victoria government in May 1946. Since then no further production took place.*

PETROLEUM CONTENTS: *Gas and oil*
PRODUCTION STATUS: *Nil*
FORMATION: *Latrobe Group*
AGE: *Late Cretaceous (T.longus)*
TRAPPING MECHANISM: *Structural*
LITHOLOGY: *Sandstone: non-marine; silty; interbedded with carbonaceous siltstone*
DEPTH TO TOP OF PETROLEUM-BEARING UNIT : *3029.0 m BSL*
POROSITY: *Up to 12%*
PERMEABILITY*: Not available*
TEMPERATURE GRADIENT: *Not available*
PRESSURE GRADIENT: *Not available*

TRAP

TRAP 6: *Eocene (P)*

DISCOVERY WELL(S): *Whiting No.1 (Whiting 'East')*

CONTENTS: *Oil*

PETROLEUM-BEARING UNIT(S)

PETROLEUM-BEARING UNIT 1: *P-250*

PETROLEUM CONTENTS: *Oil*
PRODUCTION STATUS: *Dormant*
FORMATION: *Latrobe Group*
AGE: *Late Eocene (P.asperopolus)*
TRAPPING MECHANISM: *Structural*
LITHOLOGY: *Sandstone: non-marine; partly calcareous and carbonaceous; interbedded with minor siltstone and coal*
DEPTH TO TOP OF PETROLEUM-BEARING UNIT : *1460.5 m BSL*
POROSITY: *Average 23.0%*
PERMEABILITY*: Not available*
TEMPERATURE GRADIENT: *Not available*
PRESSURE GRADIENT: *Not available*

TRAP

TRAP 7: *Eocene (M)*

DISCOVERY WELL(S): *Whiting No.1 (Whiting 'East')*

CONTENTS: *Gas and oil*

PETROLEUM-BEARING UNIT(S)

PETROLEUM-BEARING UNIT 1: *M-100*

PETROLEUM CONTENTS: *Gas and oil*
PRODUCTION STATUS: *Dormant*
FORMATION: *Latrobe Group*
AGE: *Early Eocene (M.diversus)*
TRAPPING MECHANISM: *Structural*
LITHOLOGY: *Sandstone: marginal marine; dolomitic; partly carbonaceous; interbedded with calcareous siltstone and minor coal*
DEPTH TO TOP OF PETROLEUM-BEARING UNIT : *1714.5 m BSL*
POROSITY: *Average 23.0%*
PERMEABILITY*: Not available*
TEMPERATURE GRADIENT: *Not available*
PRESSURE GRADIENT: *Not available*

TYPE: *? Gas and oil*

COMMERCIAL STATUS: *Uneconomic and undeveloped*

LOCATION: *Approximately 20 km southeast of Yarram, onshore Victoria*

STATE: *Victoria*

PETROLEUM TITLE(S): *PEP/103*

DISCOVERY WELL: *Woodside-2 (Woodside, 1957)*
- latitude: *38º37'32"* - longitude: *146º53'52"*
- discovery: *? gas and oil*
- date total depth reached: *1957*

NUMBER OF WELLS DRILLED: *1* exploration
Nil development

STRUCTURE: *Not known*
- areal closure: *Not available*
- vertical closure: *Not available*

SUBDIVISION OF PETROLEUM ACCUMULATION:
2 traps
2 petroleum-bearing units

NUMBER AND TYPE OF PRODUCING ZONES:

Nil gas	*Nil* gas/condensate
Nil gas/oil	*Nil* oil

DRIVE MECHANISM: *Not determined*

PRODUCTION COMMENCED: *Nil*

PRODUCTION INFRASTRUCTURE: *Nil*

TRAP

TRAP 1: *Early Cretaceous*

DISCOVERY WELL(S): *Woodside No.2*

CONTENTS: *Gas and oil*

PETROLEUM-BEARING UNIT(S)

PETROLEUM-BEARING UNIT 1: *? Latrobe Gp*

PETROLEUM CONTENTS: *Nil*
PRODUCTION STATUS: *? Gas and oil*
FORMATION: *? Latrobe Group*
AGE: *Early Cretaceous*
TRAPPING MECHANISM: *Not known*
LITHOLOGY: *Not known*
DEPTH TO TOP OF PETROLEUM-BEARING UNIT : *1544.1 m BKB*
POROSITY: *Not available*
PERMEABILITY*: Not available*
TEMPERATURE GRADIENT: *Not available*
PRESSURE GRADIENT: *Not available*

TRAP

TRAP 2: *Early Cretaceous*

DISCOVERY WELL(S): *Woodside No.2*

CONTENTS: *? Gas and oil show*

PETROLEUM-BEARING UNIT(S)

PETROLEUM-BEARING UNIT 1: *? Strzelecki Gp*

PETROLEUM CONTENTS: *? Gas and oil*
PRODUCTION STATUS: *Nil*
FORMATION: *? Strzelecki Group*
AGE: *Early Cretaceous*
TRAPPING MECHANISM: *Not known*
LITHOLOGY: *Not known*
DEPTH TO TOP OF PETROLEUM-BEARING UNIT : *1717.5 m BKB*
POROSITY: *Not available*
PERMEABILITY*: Not available*
TEMPERATURE GRADIENT: *Not available*
PRESSURE GRADIENT: *Not available*

ACKNOWLEDGEMENTS

We acknowledge the co-operation and assistance provided by the Department of Industry, Technology and Resources, Victoria and the operators within the Gippsland Basin permits: Esso Australia Ltd; BHP Petroleum Pty Ltd; Shell Development (Aust.) Pty Ltd; Phillips Australian Oil Company; Lasmo Energy Australia Ltd; and Australian Aquitaine Petroleum Pty Ltd.

In particular we would like to thank Mssrs Greg Short, Mike Horden, Mark Sloane, Rod Limbert and Brian Burns (Esso); Mr Bruce Thomas and Dr Keith Jackson (Shell); Mssrs Dave McDonald and Matthew Buttrick (Lasmo); Mr F.W. Vollenweider (Phillips); Mr Rene Vernet (Aquitaine); Mr Barry Hocking (BHP); Professor Allan Cook (University of Wollongong); and Dr John Saxby (CSIRO), for their part in providing us with proprietary and other data.

Special acknowledgement is due to BMR's Drs Ian Lavering and Trevor Powell for their review of the manuscript.

We would also like to acknowledge the assistance of our BMR colleagues - Brian McKay, John White, Paul Winchester, Shige Miyazaki, Rob de Nardi, Mitch Ellis, Graeme Morrison, Denis Wright and Tun U Maung.

The Figures and Plates were drawn by Joanne Jenkins, Richard Carson, Ken Barrett and Rex Bates. The graphic design by Mary Silver, the manuscript was typed by Elizabeth Walker and Felicity Evans, and re-typed by Annette Barker.

WOODSIDE OIL N.L., 1966 - Sunday Island No. 1 well completion report (unpublished).

Accumulation: a general term representing all petroleum finds irrespective of their commercial potential. An accumulation may comprise single or multiple petroleum traps all grouped on, or related to, the same individual geological structure and/or stratigraphic position.

Condensate: a liquid mixture consisting of pentanes and heavier hydrocarbons that are recoverable from a gas well through a surface-separating facility.

Crude oil: a mixture of hydrocarbons that existed in the liquid phase in underground rock formations, and remains liquid at atmospheric pressure after passing through a surface-separating facility.

Economic accumulation: a petroleum accumulation which has been declared commercial by the operator.

Liquid petroleum gas (LPG): a liquid mixture consisting of all the propane and butane that are recoverable from a gas well through a surface-separating facility.

Natural gas: a mixture of hydrocarbons and non-hydrocarbons which exist as a gas in underground rock formations.

Natural-gas liquids: a liquid mixture of LPG and condensate.

Petroleum: a gaseous and/or liquid mixture of a great many hydrocarbons and hydrocarbon compounds occurring naturally in rocks.

Petroleum-bearing unit: an interval, containing petroleum, that can be distinguished on one or more characters (e.g. lithology, stratigraphic zone, etc).

Sales gas: a mixture of methane and ethane and up to 3 per cent of carbon dioxide.

Subeconomic accumulation: a petroleum accumulation that is deemed by the operator to have significant petroleum reserves, but which has not yet been declared economically viable.

Trap: any geological condition (structural or stratigraphic, or both) which prevents the vertical or lateral movements of gaseous or liquid petroleum.

Uneconomic accumulation: a petroleum accumulation (generally a show only) that is deemed by the operator to be volumetrically insignificant and most probably non-recoverable.

PETROLEUM RESERVES AND PRODUCTION

(The estimates listed below are for the whole of the basin and not for the accumulations shown on this Plate)

REMAINING RECOVERABLE RESERVES	as of	31	12	86
Gas (Sales)		206.39 x $10^9 m^3$		
LPG		44.89 x $10^6 m^3$		
Condensate		22.44 x $10^6 m^3$		
Oil		202.44 x $10^6 m^3$		
CUMULATIVE PRODUCTION	**as of**	**31**	**12**	**86**
Gas (Sales)		66.14 x $10^9 m^3$		
LPG		41.75 x $10^6 m^3$		
Condensate		9.68 x $10^6 m^3$		
Oil		344.66 x $10^6 m^3$
