COMPILATION OF GEOLOGICAL AND BORE-HOLE DATA FROM  
SOUTH-WESTERN VICTORIA AND SOUTH EASTERN-SOUTH AUSTRALIA.

Report No. 1948/82.

INTRODUCTION.

Geographical Outline of Area.

The area covered by the report includes that part of South Australia and Victoria between Latitude 36° 00' South and Lat. 38° 30' South, and Long. 139° 30' East and Long. 142° 30' East. Military Survey Maps of the 4 Mile Series, as listed below, have been taken as the base maps for the area under discussion:-

- (1) South Australia
  - (a) Naracoorte
  - (b) Penola
- (2) Victoria
  - (a) Horsham
  - (b) Hamilton
  - (c) Portland

The area under review comprises the lands embraced within the boundaries of the following Counties:-

- (1) South Australia
  - (a) Cardwell
  - (b) Buckingham
  - (c) Mac-Donnell
  - (d) Robe
  - (e) Grey
- (2) Victoria
  - (a) Lowan
  - (b) Borung
  - (c) Dundas
  - (d) Follett
  - (e) Normanby
  - (f) Villiera (Part)

### Basis of the Report

Regional geological maps have been published for both the States concerned, by the State Departments of Mines and detailed maps as listed below are available for part of the area:-

Victoria 40 chains to 1 inch

(1) County of Follett

Parishes

- (a) Bahgallah
- (b) Dartmoor
- (c) Dergholm
- (d) Kinkella
- (e) Mumbannar
- (f) Palpara
- (g) Roseneath
- (h) Wanwin
- (i) Werrikoo
- (j) Wilkin

(2) County of Normanby

Parishes

- (a) Balrook
- (b) Drik Drik
- (c) Glenelg
- (d) Kentbruck
- (e) Killara
- (f) Myaring
- (g) Warrain

No detailed geological reports of the area have been published, although it has been reported that R.C. Sprigg of the S.A. Department of Mines has been engaged on a geological survey of Southeast South Australia, and his report is to be available towards the end of 1948.

The scope of direct geological information in the areas underlain by marine Tertiary rocks is severely limited, by very poor exposure of the underlying rocks at the surface. Under such conditions, once the scattered exposures have been examined and recorded on the map, little more can be done by surface work; the geologist is thrown back on a study of well and bore records and of the results of geophysical measurements. Considerable literature has been read and records of the principal bores in the area have been examined in detail. Tables 1 - 3 show the most important wells and bores drilled in the area.

It has been recommended that a geophysical survey of the area be conducted, to determine, if possible, any structural features which might exist at depth in this southernmost extension of the Murray River Artesian Basin, which is made up of Tertiary to Recent formations, resting, in the area under review, on a basement of Pre-Cambrian or Jurassic Rocks.

A bibliography of the principal literature consulted has been appended.

### OIL PROSPECTING IN THE AREA

One of the earliest bores drilled for oil was at Alfred Flat in the Coorong District, which was drilled in 1892 to a depth of 922 feet. Altogether 27 bore-holes have been drilled in search of oil in the area of South Australia now under discussion, with a total recorded footage of about 30,000 feet. The whole of the drilling has been carried out by local prospecting companies. In Victoria, numerous deep bore-holes have been drilled for water and some 32 bores, with a total recorded footage of approximately 20,000 feet, have been drilled for oil. The deepest of these bores was the Government bore, at Nelson, which was drilled to a depth of 7,305 feet.

The oil prospects of South Australia were investigated by Dr. A. Wade, who published his comprehensive report in 1915. A report for Commonwealth Oil Refineries, "Review of Oil Prospects in South Australia and Victoria", was published in 1938 by Dr. K. Washington Gray and I.C.H. Croll.

### GENERAL GEOLOGY

The region is generally surfaced by a thin veneer of sand, travertine and dune limestone, of Recent to Pleistocene Age.

#### Stratigraphy

##### Archean

Between Kingston and the Murray Bridge - Serviceton railway, outcrops of the Archean rocks have been mapped, and there are some exposures between the Murray and the Mount Lofty Ranges.

##### Pre-Cambrian

Crystalline schists and gneisses, granite, pegmatite and lamprophyre are recorded in bores and cliff sections on Yorke Peninsula; in the Mount Lofty Ranges; in bores and as inliers east of the Coorong; in the Upper Glenelg Valley and in the Bushy Creek area. Sedimentary rocks assigned to the Pre-Cambrian include sandstones, quartzites, slate and phyllite, and occur in the Mount Lofty Ranges; as inliers east of the Coorong; and in the Upper Glenelg.

Their relation to the crystalline rocks is obscure and relatively little is known about the series as a whole. Large scale earth movements have affected these later Pre-Cambrian sedimentary rocks throughout their extent, and many of them are strongly folded and faulted.

### Palaeozoic

#### Cambrian

In the Parish of Dergholm, County of Follett, Cambrian granites have been reported from outcrops along the Glenelg River about 6 miles north-northeast of Dergholm township, and also from scattered locations along the upper reaches of Salt Creek. Similar Cambrian granites outcrop along Laidlow's Creek, just south of Dergholm township, in the Parish of Roseneath. The granites are also found near Graham's Swamp, 4 miles southwest of Dergholm. A small exposure of Cambrian diabase occurs about 3 miles south of the township.

The fossiliferous marine beds of Cambrian age, consisting essentially of limestone and dolomites, have shared in the folding and faulting that have affected the older foundations.

#### Ordovician

Steeply folded sandstones, shales, grits, slates and mudstones of Lower Ordovician age are exposed in the eastern highlands region between the 142nd. and 145th. meridians. In the Parish of Dergholm, Ordovician slate and hornblende biotite gneiss have been reported from near the Glenelg River, just south of the outcrops of Cambrian rocks. Acutely folded indurated slates and sandstones of Ordovician age outcrop along the Glenelg River, 3.1/2 miles east-southeast of Dergholm township. The fossiliferous beds of the eastern highlands lie conformably on the unfossiliferous Cambrian strata. There are no proven Ordovician rocks in South Australia, although rocks occupying a narrow belt on the northern coast of Kangaroo Island may possibly be of this age.

Silurian and Devonian rocks are not represented in the area, which carries no trace of marine sedimentation throughout the whole of the later part of Palaeozoic time.

#### Permo-Carboniferous

A widely distributed glacial tillite with fluvio-glacial conglomerates and agillaceous sandstone has been classed as Permo-Carboniferous age. The tillite is recorded from a number of localities ranging from Yorke Peninsula (S.A.) to Beechworth (Vic.), so that it would seem that present exposures are remnants of a much more widely distributed deposit. A maximum thickness of 1,030 feet is estimated in South Australia and not more than 2,000 feet in Victoria.

The tillite is known to occur at depth below Hindmarsh Island at the Murray Mouth, and at Alfred Flat between the Coorong and Tintinara, where it has been found by boring, but does not outcrop. In the Coorong Oil Company's bore drilled in 1922, 421 feet of the tillite were penetrated before Pre-Cambrian slates were entered at 924 feet. No coal measures, nor any marine deposits of Permo-Carboniferous age have been found at any place, associated with the tillite.

The tillites rest upon Pre-Cambrian and Cambrian foundations and are overlain in some places by marine Tertiary beds.

### Mesozoic

#### Jurassic

Green felspathic sandstones, sandy shales and conglomerates, to which a Jurassic age is assigned, are met in numerous boreholes and exposures in the area. These rocks are of lacustrine origin and throughout southern and eastern Australia no marine Jurassic rocks are known. A marine facies in the Jurassic is unlikely since both at Robe and in the Otway Ranges, it is lacustrine, and there is a probability therefore, that land was present to the southwest in Jurassic times. Bituminous coals of moderate quality occur in thin seams and lentils. The beds are commonly horizontal, but frequently show local dips of  $10^{\circ}$  -  $30^{\circ}$ . There is no clear evidence of folding and such disturbance as is shown is probably due to Tertiary faulting. The sands which constitute the principal aquifer of the Grant Artesian Basin in the north-eastern part of South Australia are of Jurassic age. No marine fossils have been recognised in the sands, but fragments of lignite occur in them.

The Jurassic coal measures which outcrop in Western Victoria in the Casterton-Coleraine district extend westwards below the surface into South Australia, where their presence has been proved by the deep borehole near Robe, which penetrated the Jurassic sediments at 1,475 feet. No other borehole in the southeastern region of South Australia has penetrated to a sufficient depth to reach these measures which are presumed to exist in depth beneath a large part of the area lying to the south of the railway between Naracoorte and Kingston, although they do not underlie the Tertiary beds close to Kingston itself. The borehole drilled near Lake Cooie in Victoria, after passing through Tertiary sediments, entered the Jurassic measures at 509 feet and continued in them to the bottom of the hole at 1,171 feet. The rocks consist of thin bedded greenish or bluish grey shales and fine grained argillaceous sandstones with a few thin beds of limestone and some thin coal seams. These Jurassic beds probably extend southwards beneath the Recent and Tertiary cover, from the exposures at surface in the Casterton district.

Generally, beds of Jurassic age were deposited in a broad belt of low-lying swampy land, probably on the margin of the Jurassic sea, the accumulation of the sediments proceeding gradually with the slow submergence of the swampy zone. No evidence has been found yet of marine transgression over this swampy depression while Jurassic sedimentation was in progress.

No Triassic or Cretaceous rocks are known to exist in the region, even at depth, nor any representatives of the lowest division of the Tertiary.

### Cainozoic

The next series to be deposited were the alternating sands, gravels and lignites or lignitic clays, covered by the limestones containing many fragmental remains of polyzoa, echinoderms and corals, with a few brachiopods and lamellibranchs.

It would appear from the succession of beds that in Mid-Tertiary time there was a widespread submergence of the southern part of the continent, the lowest beds indicating deposition in coastal swamps or estuaries, subject to periodical submergence beneath shallow sea-water, and the upper beds suggesting conditions of submergence beneath a sea of moderate depth with formation of marine limestones. This deeper water of the ancient Murravian Gulf extended far inland, forming a great gulf now crossed by the River Murray and its tributaries. Towards the end of the Tertiary period the submerged area rose and this process of emergence has continued until the present day. During Pleistocene time the successive positions of the strandline were marked by dune ridges oriented in general parallelism with the present coast line. The latest phase of the general elevation of the region was marked by the volcanic activity at Mount Schank, Mount Gambier, Mount Burr, Mount Muirhead and the craters in which Lakes Leake and Edward lie. Between the dune ridges there have been deposited discontinuous shallow beds of clay, silt and peaty marl from the earliest period of emergence down to the present day.

#### Correlation

There has been much dispute about the correlation of the Tertiary deposits of southern Australia. A broad lithological division is possible and avoids the necessity of adopting any one set of age determinations. However, for the purpose of this report, the ages as determined by Miss Crespín and as set out in her report on the Tertiary rocks of Gippsland, have been adopted.

The lignitiferous series at the base of the Tertiary, is regarded as being in general, of fluvio-lacustrine origin, but locally, there are marine intercalations. Occasional foraminifera have been recorded from several bores, which have penetrated this series. The series has been assigned to the Anglesean Stage, of Lower Middle Miocene age. The overlying series of marine foraminiferal and polyzoal limestones and marls attain a considerable thickness, reaching 2,100 feet at Portland. At the base of this marine series in the Gippsland area, there is a bed of oil-bearing glauconitic sandstone, but this horizon is not found in the south-west. Parts of the marine series bear thin streaks of lignite, but the development is not to be compared with that of the main lignitic series. The marine series has been placed in the Balcombian and Janjukian Stages of Middle Miocene age.

The sharp lithological break between the sands and the limestones has been cited as proof of an unconformity, but the foraminifera of the marine intercalations in the sands and of the limestones do not suggest any hiatus. The fauna of the Balcombian, Janjukian and Anglesean Stages have been shown to be closely related, and are regarded as being of Middle Miocene age.

In the area under review, the marine series is overlain by extensive basalt flows referred to as the "Newer Basalt"; or by recent sands and travertine. The basalts are of late Pliocene to Pleistocene age.

The Tertiaries attain a thickness of about 1,450 feet in the Robe bore, while at Portland the Polyzoal series alone attained a known thickness exceeding 2,100 feet. At Nelson, the bore passed through approximately 900 feet of the Polyzoal series, and was still in the Tertiary lignitiferous series at 7,305 feet.

#### Localities

The principal Tertiary exposures in the area are at Mount Gambier and the Glenelg River cliffs from Casterton to Nelson. In the Parish of Dartmoor, north of Dartmoor township, ligneous sands and clays of the lignitiferous series outcrop along the Glenelg River for approximately 2.3/4 miles.

#### General Section

A generalised section, showing approximate age and sequence of strata met with in the area, can be given as follows. In no one place can all of these beds be found in association. Some of the strata shown are only to be found in certain localities; others show considerable variation as they are traced from place to place.

1. Sandhills, blown sands and alluvium - Recent.  
These include the shifting sands of the coastal sand dunes and the loose sand which extends far inland and forms the sand dunes of the interior.
2. Older sandhills, loose or partly consolidated - Recent to Pleistocene. The blown sands of (1) especially the more calcareous types tend to become cemented and consolidated in the course of time. During this process, the old structure is well preserved.
3. Travertine - Recent to Pleistocene.  
This is a more or less massive limestone. It varies from compact and solid to a cellular or almost cavernous structure. It covers vast areas of country, but is nowhere more than a comparatively few feet in thickness.
4. Lateritic Ironstone.  
Where the blown sand cover is siliceous rather than calcareous, deposits of limonite are formed, again only a few feet thick at the most.
5. Fossiliferous limestones - Pliocene.  
Underneath the material described as (1), (2), and (3), there occurs in a few isolated places, a cream coloured limestone, rich in marine fossils.
6. Sands, Clays and Thin Lignite Beds.  
In other places, under the same beds, occurs a series of loose sands containing marl and clay, sometimes lignitic in character. These beds are aeolian and shallow water types and are subject to rapid lateral variations and so vary a good deal in thickness.

7. Miocene (Janjukian) limestones and flint beds.  
This fossiliferous marine limestone series is of distinctive buff color. The limestones are associated with beds of nodular flints and bedded cherts. The series, in places, is pierced by -
8. Basalts, which have been poured out of the extinct volcanoes of the Mount Gambier district, in Upper Pliocene to Pleistocene time.
9. Lignitic sands and clays (Anglesean) - lignitiferous series of Lower Middle Miocene age.
10. Greenish-grey shales and fine grained argillaceous sandstones, sandy shales and conglomerates, in which occur thin seams of bituminous coal - Jurassic age.
11. Glacial beds, tillites - Permo-Carboniferous age.  
Met at 503 feet in bore in County of Cardwell.
12. Steeply folded sandstones, shales, grits, slates and mudstones of Ordovician age.
13. Granites, diabases and fossiliferous limestones and dolomites all of Cambrian age.
14. Crystalline schists, sandstones and quartzites - Pre-Cambrian

#### GEOLOGICAL HISTORY

The geological history of the Murray River Artesian Basin is concerned with earth movements that are more complex than those involved in a mere simple subsidence and subsequent uplift. The subsidence began in Tertiary time and followed upon a long period of erosion during which a large part of southern Australia was reduced to the condition of a peneplain. The muds and clays containing lignite and the beds of sand and gravel that are characteristic of the lower horizons and are interbedded with marine strata, indicate oscillations of level, with alternating emergence and submergence of coastal swamps. The general tendency however, was one of subsidence and as the sea became deeper, the fragmental polyzoal limestone (Janjukian) was deposited in a broad gulf. This Tertiary sea also probably covered a wide expanse of Palaeozoic and Mesozoic rocks in western Victoria, although most of the sediments deposited in that sea have been stripped by erosion from the foundations outcropping near Casterton, Coleraine and Hamilton. Towards the close of the Tertiary there was a general uplift of Southern Australia.

Since the lower Palaeozoic there have been no large scale folding movements. From the Upper Devonian to the present day the area has been occupied by dry land or lakes and swamps, with only partial and occasional marine invasions, of which the Middle Miocene was the most extensive. A series of fissure eruptions, giving rise to the "Older Basalt" preceded this marine invasion, and a further series producing the "Newer Basalt" was associated with its termination.

The marine Tertiaries extend over a large area beneath the "Newer Basalt", while the Jurassic is present over a wide area, but not everywhere, beneath the Tertiaries. The ancient foundations of Pre-Cambrian age, consisting of slates, quartzites, crystalline limestone and intrusive bodies of granite and felspar porphyry, do not outcrop at any place in South Australia to the south of the railway between Naracoorte and Kingston. They have been reached by deep boreholes in the vicinity of Kingston.

The change of slope near the hundred fathom line, which is adduced as evidence of faulting, is present all round the Australian continent and marks the edge of the "Continental Shelf". When true scale profiles of the sea floor are prepared, it is seen that no abrupt fault scarp is necessary to explain the soundings. A gentle down-warping is sufficient. The average fall of the sea floor from the shore to the 100 fathom line off Cape Bridgewater, is 5 fathoms per mile, giving a slope of much less than one degree ( $0^{\circ} 20'$ ); beyond the 100 fathom line, the soundings show a fall of 30 fathoms per mile, which still, however, gives a slope of only 2 degrees. The slope beyond the 100 fathom line is considerably greater off other parts of the Australian coast, being 5-6 degrees off Gabbo Island and almost 7 degrees off Albany. The possibility of faulting is not excluded, but it remains quite hypothetical. It has been claimed that the land between Portland and Mount Gambier is divided into strips by persistent faults or abrupt down-warps parallel to the 100 fathom line, but on Cape Nelson, Cape Bridgewater and in the Glenelg River evidence for such structural control has not been found. There is some faulting on both Cape Nelson and Cape Bridgewater, but on the latter, the only fault whose direction can be measured, runs S 70 W - quite oblique to the 100 fathom line.

#### TOPOGRAPHICAL FEATURES OF THE AREA.

The topography of the South Australian region generally is that of a former submarine plain that has emerged from the sea by crustal upwarping; and has preserved, in the absence of active erosion, a succession of dune ridges capped with calcareous dune sand and fixed by the partial solution and redeposition of Calcium Carbonate. Between these successive dune ridges there are valleys most of which are nearly flat bottomed and broad when compared in width with the ridges. The valley bottoms are known to slope to the westward, and each valley is higher than that lying to the west of it. The ridges rise in general to heights of less than 200 feet above the valleys. Modifications of the topography have been affected at a few places by volcanic action which has given rise to accumulations of ash and scoria associated with other ejectamenta from the centres of violent explosion.

It appears probable that the emergence of the coastal region has taken place since the close of the Pliocene period in a series of uplifts between which there have been periods of stability. The dune ridges are oriented in general parallelism with the coastline of today, trending in a direction bearing north-north west - south-southeast, from the area facing Lacepede Bay to that behind Lake Bonney, but becoming less well defined and veering to adopt an approximately east - west trend to the south of Mount Gambier.

The Tartwaup Fault extending in a general southeast direction from near Millicent to Tartwaup has left its mark on the topography, even if modified by erosional forces. The elevated region in the eastern part of the Hundred of Comaum and the adjoining portion of Victoria, may possibly be a block left standing at a higher level while the surrounding country has showed in general, subsidence. Yet it is not known whether the margins of the elevated block are determined by faulting or whether the higher land, on the other hand, forms the crest of a structural dome. The surface level of this relatively high area falls in all directions - northwards towards Mosquito Creek; eastwards towards the Glenelg River; southwards towards the low-lying areas east of Penola and westwards towards the Rocky Castle swamp and low lying areas north of Glen Roy. It is known that faulting has occurred in the Naracoorte district, but the relationship of the high country in the Hundred of Comaum to any tectonic movements connected with this faulting has not been determined by detailed mapping. This late faulting took place, so far as can be seen, after the close of the Tertiary period. The older faulting, probably responsible for the truncation of the deeply-seated Jurassic sediments on their northern limb has left no mark on the topography.

The Robe bore, drilled to a depth of 4,504 feet, did not reach the foundations that underlie the Jurassic sediments; whereas the borehole near Kingston, T.D. 2,660 feet, reached the Pre-Cambrian bedrock at 484 feet from the surface. The Jurassic beds have been reached, as mentioned above, at a depth of 509 feet from the surface in a borehole 1,171 feet deep, drilled near Lake Coole. These results obtained from boreholes indicate the probable existence of a major fault to the south of the Naracoorte - Kingston railway, and it seems probable that the age of the faulting is Pre-Tertiary. On the other hand, the effects of normal deposition and erosion could explain the conditions as outlined in these boreholes, and so faulting is not regarded as being necessary.

#### DETAILED CONSIDERATION OF THE AREA.

The underlying rocks of the area being considered, are almost everywhere obscured by superficial deposits of sand and travertine. In the southeastern district of South Australia, the surface is almost entirely occupied by low sandy ridges running roughly parallel with the coast and rarely exceeding an elevation of 200 feet. This type of country extends as far as 70 miles inland eastward from the coast and about 300 miles from north to south. This part of the country is devoid of any natural system of drainage, except by sinkholes and underground channels in the limestone near Mount Gambier. Inland, the blown sand is an almost general surface cover. Travertine forms a large part of the surface cover in the extreme southeast of South Australia around Mount Gambier and northwards towards Kingston. Travertine is rare in the country east of the Coorong.

Apart from the mapping by R.A. Keble and E.A. Rudd of areas in the Hundred of Blanche, the surface geology of the area under review is known only in general terms. In the Hundred of Blanche, omitting the superficial deposits, the stratigraphical sequence and thickness of the horizons are given as:-

- (a) Polyzoal limestone and dolomites (Janjukian) -  
900 feet measured in outcrop by Keble
- (b) Lignitic sands, clays and gravels (Anglesean) -  
1968 feet in Associated Bore  
1838 feet in Knight's Dome No.2 Bore.

In the district north of the Kingston - Naracoorte Railway, the sandy cover is fairly shallow and outcrops of igneous rocks are very numerous. South of the railway, no granite or other Pre-Cambrian rocks have been observed to break the continuity of the surface cover.

Exposures along the Glenelg River and the results of Boring operations show that a large part of the area is underlain by marine polyzoal limestone, below which are the lignitiferous sands and clays of lacustrine origin with occasional marine intercalations. These beds represent a southern extension of the Miocene deposition in the Murray River Artesian Basin. Eastward of the Coorong District in South Australia for about 100 miles, granite is exposed at the surface at a number of points. "The Coorong" is a long narrow lake running south-eastward parallel to the coast from Lake Alexandrina, for approximately 90 miles. It is separated from the sea only by a ridge of sand dunes. In the adjacent district which has been called the "Coorong District" several long narrow ridges running roughly parallel to the present coast line are separated by low lying flats. This type of topography extends inland for some 50 miles. The ridges consist of semi-consolidated calcareous dune sand with a hard travertinized coating, while the flats are underlain by recent marine deposits. The ridges are old coastal dunes left behind by successive retreats of the sea.

Between the belt of granite outcrops and the sea, bores show that the Tertiary marine rocks vary greatly in thickness. In some places (Kingston district) Tertiaries overlies the Pre-Cambrian directly; in others (Coorong) they are separated from it by Permo-Carboniferous tillite; while further south at Robe the Tertiaries are much thicker and overlies Jurassic sandstones.

The greatest known thickness of marine Tertiary limestones in the region, is at Portland where a bore proved over 2,100 feet, of which the basal part contains some glauconite. These beds are very little disturbed. The bore at Nelson proved 7,305 feet of Tertiary sediments, where the lignitiferous series was entered at 989 feet; thus proving 6,316 feet of the Anglesean Stage. Shallow wells at Tantanoola and in the Hundred of Young, northwest of Mount Gambier, proved not more than 100 feet of limestone overlying the lignitiferous series. The Knight's Dome No.1 and Associated Bores entered the lignitiferous series at 80 feet and 142 feet respectively and the latter bore proved approximately 2,000 feet of the lignitiferous series without reaching the Jurassic. The basal 3,000 feet of strata in the Robe bore are assigned to the Jurassic on the basis of lithological analogies with the Jurassic sandstones of the Casterton - Coleraine district; these beds do not carry any evidence of marine conditions. The Jurassic beds may continue under the Mount Gambier district and further south, but this is merely surmise, since no borehole to date, has penetrated the whole series of Tertiary sediments in this southern district. Along the Glenelg River, about 4 miles north of Dartmoor township, in the Parish of Myaring, County of Normanby, Jurassic sandstones are exposed at the surface.

This is the most southerly reported outcrop of Jurassic sediments.

The sedimentary strata overlying the Pre-Cambrian rocks are, as far as can be observed, horizontal or at most, so slightly tilted from the coast inland, that the angle is too small to measure. They appear to be almost totally unaffected by any folding.

The deep basin as shown to exist in the southern part of the area under review, may be considered to be an extension of the Murray River Artesian Basin, with a possible structural barrier of Jurassic sediments extending from Robe through Comaun to Casterton.

-----

DRILLING

A good deal of drilling both for oil and for water, has been done in the region under review. Tables 1, 2, and 3 list the principal bores and wells drilled in the area.

Records of Bores and Wells

The area under review has been divided into three regions:-

- (a) Wimmera
- (b) Glenelg
- (c) South Australia

The records of bores and wells drilled in these regions have been divided into four parts:-

- (1) Table showing bore number, location, name of bore, year drilled, depth
- (2) Table showing bore number, location, elevation, depth, lithological subdivisions, etc., of strata penetrated in bore
- (3) Table showing name of bore, bore number, location, name of Company, depth, report reference to bore.
- (4) Logs of Bores.

Explanatory Notes to Tables.

Table 1. Records of bores and wells showing numbers, locations etc.  
 B.M.R. Number: The number which has been allotted for the purpose of this report, to each bore and well in the area.

Regional Number: The number which was allotted to bores and wells by C.S. Gloe in the publication "The Underground Water Resources of Victoria". Vol. 1.

Parish or Hundred: The name of the Parish or Hundred in which the well or bore is located.

Location:

Wimmera Region: In most cases the locations of the bores can be referred only to the Crown Allotments in which they were put down.

Glenelg Region: Nearly all the bores listed were put down by the Mines Department, hence their locations can be defined with some accuracy.

South Australia Region: Locations have been referred to Sections and Hundreds in which the bores were drilled.

**Name or Owner:**

Wimmera Region: Either the name by which the bore or well is known, or the owner's name.

Glenelg Region: The name and number given to the bores by the Mines Department. The Report

Reference gives the reference to the report in which the records of the bores were published.

Abbreviations used are:-

A.R. - Annual Report.

B.R. - Boring Records.

Depth of Bores and Wells: The depth in feet from ground surface to the bottom of each bore or well.

Table 2.

Records of bores and wells showing lithological subdivision etc, of strata penetrated in bores or wells.

R.L. Surface: Reduced Level, or height in feet above sea level of the ground surface. In each case, levels shown are to the nearest foot only. Depths recorded to lithological horizons are from ground surface.

Table 3.

Records of names of bores, B.M.R. Numbers, etc.

Name of Company: Name of Company for whom the bore was drilled.

Table 4.

Bore Logs.

Logs of bores put down by the Mines Department in the Glenelg Region have been published in the Annual Reports and Boring Records of that Department. The logs of the principal bores have been selected and are recorded under Table 4. Unless otherwise stated, all logs listed for the Glenelg Region are drillers' logs.

Strata: Glenelg Region

The rock types met with in the bores are as follows:-

- (a) Bores in the Parishes of Casterton, Carapook, Muntham, Coleraine, Hilgay, Merino, Sandford, Bahgallah and Mocamboro struck Jurassic sandstones and shales beneath a cover of Cainozoic clays, sands and gravels, which ranged in thickness from 14 - 82 feet.
- (b) Bores in the Parishes of Dartmoor and Glenelg struck two main series:
  - (i) limestones, marls and clays (Janjukian) overlying
  - (ii) ligneous sands and clays (Anglesean)

- (c) Bores in the Parishes of Portland, Heywood and Yulecart penetrated soil, sand and clay before entering Tertiary limestone and marls.

Strata: South Australia region

- (a) Some bores in the Counties of Cardwell and Mac-Donnell reached Pre-Cambrian bedrock.
- (b) Bore in the County of Robe passed through the polyzoal limestone series, the lignitiferous series and bottomed in the Jurassic.
- (c) Bores in the County of Grey struck two main series as for (b) above - limestones and marls overlying lignitic sands and clays.

Whenever possible, lithological sub-divisions have been made of the various rock types encountered in the bores listed in Table 2.

South Australia

(1) The Coorong, County of Cardwell

Seven boreholes have been drilled near Alfred Flat in the Coorong District in search of oil. Four of these reached Pre-Cambrian bedrock at depths between 190 and 587 feet, after passing through Tertiary polyzoal limestones, ~~gauconitic~~ foraminiferal marl and lignitic sands and clays. One went to 924 feet before striking the Pre-Cambrian, but had met Permo-Carboniferous tillite at 503 feet.

A summary of these bores is shown below:-

| Bore<br>B.M.R. No. | Bore<br>T.D. | Depth to Surface<br>of Pre-Cambrian | Remarks               |
|--------------------|--------------|-------------------------------------|-----------------------|
| 201                | 922          | 565 feet                            | Pre-Cambrian marble   |
| 202                | 931          | 924 "                               | 503-924 feet. Tillite |
| 203                | 650          | 190 "                               | Pre-Cambrian Phyllite |
| 204                | 656          | - )                                 | Abandoned in Tertiary |
| 205                | 701          | - )                                 |                       |
| 206                | 606          | 581 feet                            | Pre-Cambrian slate    |
| 207                | 450          | 400 "                               | Pre-Cambrian schist   |

Samples collected from Bore B.M.R. No. 207 were examined by Commonwealth Palaeontologist, who reported as follows:-

|             |   |
|-------------|---|
| 0 - 36 feet | Sub-Recent to Pleistocene                       |
| 36 - 200 "  | Upper Pliocene (Werrikooian)                    |
| 200 - 234 " | Polyzoal limestone (Middle Miocene)             |
| 234 - 244 " | Glaucinitic foraminiferal marl                  |
| 244 - 400 " | Lignitic sands and clays - lignitiferous series |
| 400 - 450 " | Pre-Cambrian bedrock.                           |

It appears from the records of these bores, that bedrock, almost certainly of Pre-Cambrian age, lies at no great depth beneath the Tertiary and Recent sediments, in the Coorong district.

## (2) County of Buckingham

One bore was drilled in the Hundred of Stirling and five in the Hundred of Tatiara, all being water bores. Stratigraphic and lithologic information of these bores is somewhat limited. Five of the bores bottomed in Tertiary limestone or calcareous sandstone, whilst the sixth known as the Bordertown Bore bottomed in Pre-Cambrian bedrock, consisting of coarse quartz-mica schist and mica schist. The bedrock was entered somewhere between 567 and 601 feet. As in the case of the Coorong bores, sediments of Jurassic age were not encountered in any of the bores. Tertiary beds were found to be overlying Pre-Cambrian rocks in the one bore which pierced the complete section of Tertiary sediments.

A Summary of the boreholes is as follows:-

| Bore<br>B.M.R. NO. | Hundred  | Bore<br>T.D. | Remarks                          |
|--------------------|----------|--------------|----------------------------------|
| 208                | Stirling | 269 ft.      | Bottomed in calcareous sand      |
| 209                | Tatiara  | 180 "        | Bottomed in coralline limestone  |
| 210                | Tatiara  | 156 "        | " "                              |
| 211                | Tatiara  | 130 "        | Bottomed in calcareous sandstone |
| 212                | Tatiara  | 148 "        | " "                              |
| 213                | Tatiara  | 601 "        | Bottomed in Pre-Cambrian bedrock |

## (3) Kingston, County of Mac-Donnell

A group of five bores has been drilled around Kingston, some 50 miles down the coast from Alfred Flat, in the search of oil. Records of these bores showed that here also, the Pre-Tertiary land surface lay at shallow depth. Jurassic rocks were not encountered in any of the bores.

A Summary of the boreholes is as follows:-

| Bore<br>B.M.R. No. | Bore<br>T.D. | Depth to Surface<br>of Pre-Cambrian | Remarks                                 |
|--------------------|--------------|-------------------------------------|---|
| 214                | 1,365        | 281 feet                            | Pre-Cambrian slate                      |
| 215                | 1,170        | no adequate records                 |   |
| 216                | 2,660        | 484 feet                            | Pre-Cambrian limestone<br>and quartzite |
| 217                | 204          | -                                   | Bottomed in Tertiary                    |
| 218                | 466          | 402 feet                            | Pre-Cambrian slate                      |

In Bore B.M.R. No.214, normal Tertiary sediments, comprising polyzoal limestone with flints, and the usual underlying lignitic clays and sands, were penetrated to a depth of 281 ft. At this depth, the drill entered thin bedded slate of Pre-Cambrian age, and remained in rocks of this character to the bottom at 1,365 feet.

In Bore B.M.R. No.216, after passing through Recent and normal Tertiary sediments, at 484 feet from the surface, the bore entered steeply inclined beds of grey limestone with bands of quartzite and veinlets of calcite and quartz containing disseminated pyrite, almost certainly of Pre-Cambrian age. Boring was continued in the rocks of this type until a T.D. of 2,660 feet was reached. From bore records it appears that the lignitiferous series was entered at 300 feet and continued to 484 feet.

Samples collected from Bore B.M.R. No.217, have been examined and reported on as follows:-

0 - 48 feet    Recent to Pleistocene, and certainly not  
                  older than Upper Pliocene  
48 - 204    "    Upper Pliocene (Werrikooian)

This bore was abandoned on account of the large flow of artesian water, estimated to be 36,000 gallons per hour, struck at 187 feet.

Samples collected from Bore B.M.R. No.218, have been examined and reported on as follows:-

0 - 16 feet    Recent to Pleistocene  
16 - 103    "    Upper Pliocene (Werrikooian)  
103 - 402    "    Middle Miocene

A break in the series is reported at 103 feet.    Slate bed-rock was penetrated at 402 feet.

#### (4) County of Robe

One deep bore was drilled in search of oil, and two shallow holes were waterbores.

## (a) Robe Bore; Bore B.M.R. No.219.

In 1915, a borehole, which ultimately attained a depth of 4,504 feet, was started by S.A. Oilwells Company at a site on the Woakwine Range, some 7.3/4 miles by road from Robe. (Section 714, Hundred of Waterhouse). The Woakwine Range is a consolidated, calcareous dune ridge of Pleistocene age and the bore site was at an elevation of 127.5 feet above sea level. Boring was carried out with a percussion drill which penetrated a thin superficial crust of travertine and then shell sand to a depth of 145 feet. Two feet of shelly limestone followed and at 147 feet the bore entered the typical polyzoal limestone which continued to 510 feet. Then followed nearly 1,000 feet of interbedded sands, clays and gravels. Some of the clays were green while others were grey, brown and black. Sharks' teeth and corals were found in sands occurring between 635 and 645 feet. Several pyrite layers, up to 1/2 in. thickness, were passed through, and carbonized wood, like charcoal, was obtained from shale between 1,000 and 1,002 feet. The last actual sand of this series occurred at 1,475 feet, and was bedded between greenish-grey to bluish-grey shales. Possibly the Jurassic coal measures were entered at this depth. The beds penetrated in the rest of the borehole were mostly greenish-grey shales and fine argillaceous sandstones with some seams of bituminous coal and traces of carbonaceous matter throughout. Definite seams of coaly matter were reported at 2,830 feet; 2,840 feet; 2,845 - 2,855 feet; 3,100 feet; 3,141 - 3,167 feet; 3,200 feet; 3,305 feet; 3,473 feet; (a 3 ft. seam) but not below 3,642 feet. This latter series was assigned, partly on the ground of lithological analogy with other bores and outcrops, and partly on account of the character of the included coal, to the Jurassic. The series is evidently an extension of the rocks of Jurassic age, which outcrop in the Casterton area, but are concealed beneath the Tertiary and Younger rocks in the South Australian territory. No strata of marine origin were found when once the Jurassic rocks were entered.

## (b) Bore B.M.R. No.220

This bore was drilled to a depth of 186 feet, at a site in Section 242, Hundred of Comaum, south of Naracoorte, for the purpose of draining Rocky Castle Swamp. The bore bottomed in fine sand of Tertiary age.

|             |  |
|-------------|--|
| 0 - 20 feet | Surface Sands                              |
| 20 - 165 "  | Polyzoal limestone                         |
| 165 - 186 " | Clay and sands of the lignitiferous series |

## (c) Bore B.M.R. No.221

The bore known as Government Bore No.1, was drilled for water at a site in the Hundred of Naracoorte, to a depth of 488 feet. The bore bottomed in black lignitic clay.

(5) County of Grey

Ten boreholes have been drilled in search of oil, and a further six bores, drilled for water, have been selected for discussion.

## (a) Mount McIntyre; Bore B.M.R. No.222

Boring was carried out on the northern slope of Mount McIntyre, Section 9, Hundred of Riddoch, 50 miles S 60 E from Robe. The boring was carried out with a rotary drill, by the Adelaide Oil Exploration Company, and reached a total depth of 1,045 feet. The bore bottomed in Tertiary sand, below the base of the polyzoal limestone. Several dykes or sills of basalt were penetrated. The bore was sunk with the object of ascertaining whether there had been any accumulation of oil as a result of the possible effect of basaltic intrusions on Tertiary or Jurassic coal measures; either by destructive distillation of the organic matter in these measures, or by the disruption of the strata by igneous forces, with the creation of physical conditions favorable to the concentration of any oil that might be disseminated through the sedimentary rocks.

Mount McIntyre is capped with vesicular basalt, but there is no volcanic vent in the immediate vicinity of the borehole. The basalt occurs within a broad zone that extends for many miles in a direction parallel with the continental margin in this region, and within which there have been many centres of eruption including Mount Schank and Mount Gambier. This zone of basaltic volcanic action reaches Mount Muirhead, near Millicent, at its northwestern limit.

## (b) Mount Burr; Bore B.M.R. No.223

A bore was drilled for water at Mount Burr, in the Hundred of Riddoch. T.D. 425 feet.

The Tertiary stages met in the bore were:-

- (i) Werrikooian (Upper Pliocene) 19 - 148 feet
- (ii) Janjukian (Middle Miocene) 148 - 425 feet

The Werrikooian is represented in the bore by fossiliferous dune limestone, tuffaceous and calcareous sandstone and a gritty limestone. Similar limestones are recorded from bores at Kingston and in some of the Dartmoor bores.

The Janjukian rocks met in the bore consist of hard white limestone and flints, passing downwards into chalky bryozoal limestone. Similar beds are also found in bores and outcrops in southeastern South Australia and southwestern Victoria. Apparently a disconformity exists at 148 feet, where the beds underlying the Upper Pliocene are Middle Miocene in age.

## (c) Bore B.M.R. No.224

A water bore was drilled in Section 555, Hundred of Mount Muirhead and known as Cheese Factory No.1 bore. T.D. 575 feet. The bore passed through Tertiary limestone, with hard flinty bands, and bottomed in Tertiary limestone with layers of marl.

## (d) Tantanoola; Bore B.M.R. No.225

On completion of the Robe bore, the drill was moved to a site within Section 195, Hundred of Hindmarsh, on the up-throw side of the Tartwaup Fault, close to the fault scarp known as the Up and Down Rocks, and 3 1/2 miles to the east-southeast of Tantanoola, or about 5 1/2 miles southeast of Robe. The bore was drilled by S.A. Oil Wells Company and reached a depth of 1,532 feet.

- 0 - 392 feet Polyzoal limestone (Janjukian)  
 392 - 1,532 " Sands and clays assigned to the lignitiferous series.

The upper part of this latter series contained evidence of marine intercalations. Sharks' teeth were obtained from red sand at 460 feet and corals were reported when a depth of 573 feet was reached. At 581 feet, the drill entered a series of interbedded dark clays and sands or gravels, some of the clay being lignitic in character. This series continued to the bottom of the hole. The bore was sunk as a test for accumulation of oil against a fault plane.

(e) Hundred of Young

Three shallow boreholes, situated within the Hundred of Young, were drilled in an attempt to drain the Dismal Swamp by letting the surface water enter the beds of permeable sand. All bores bottomed in clays and sands assigned to the lignitiferous series.

A Summary of these bores is as follows:-

| Section | Bore<br>B.M.R. No. | Bore<br>T.D. | Polyzoal Series | Lignitic Series |
|---------|--------------------|--------------|-----------------|-----------------|
| 164     | 226                | 157          | 16 - 109 feet   | 109 - 157 feet  |
| 217     | 227                | 141          | 4 - 50 "        | 50 - 141 "      |
| F       | 228                | 133          |                 |                 |

These bores proved a thin cover of the Janjukian polyzoal series, overlying the usual lignitic sands and clays.

(f) Hundred of Blanche

(1) Bore B.M.R. No. 229

In section 150, in the northwest corner of the Hundred, a bore was sunk by Producers' Oil Wells at a site on the southern (Downthrow) side of the Tartwaup Fault. T.D. 1,220 feet.

- 0 - 210 feet Polyzoal limestone  
 210 - 1,220 " Clays, sands and gravels assigned to the lignitiferous series.

(11) Associated Bore; Bore B.M.R. No. 230

In 1923, a borehole was drilled by Associated Oil Corporation at a site within Section 301, 8 miles to the northwest of Mount Gambier. T.D. 2,110 feet.

- 0 - 34 feet Recent to Pleistocene  
 34 - 142 " Dolomitized polyzoal limestone  
 142 - Bottom Clays and sands containing marine intercalations with sharks' teeth and corals - assigned to the lignitiferous series.

At 381 feet, there was a silt with corals and sharks' teeth. At 2,095 feet, the drill passed through a bed of fine carbonaceous sandstone with a molluscan and foraminiferal fauna.

### (iii) Knight's Dome

A detailed geological survey carried out by R.A. Keble, of the Hundred of Blanche, was held to have established the presence of a closed anticlinal structure of somewhat irregular form, in the Tertiary Janjukian formation, near the Burnda Siding on the Mount Gambier - Beachport Railway, about 5 miles to the west-northwest of Mount Gambier. This structure became known as Knight's Dome or Burnda Anticline. The "dome" is a long narrow anticline, the axis of which is nearly North - South. The eastern limb is much steeper than the western. There is definite indication of closure of the structure at its southern end, and strong presumption of a similar closure towards the north as well, though in the latter direction, the Tertiary rocks are hidden beneath later accumulations of drift sand.

It has been reported of Knight's Dome that:-

- (a) There is still no unquestionable proof of the existence of oil in the southeastern region at any place, either disseminated through the Tertiary or Jurassic rocks or concentrated in any part of these rocks.
- (b) The rocks of the Tertiary system in this region are not unfavourable for the existence of commercial accumulations of oil, as regards either age or lithological character.
- (c) Structural conditions due to folding and faulting and suitable for the concentration of oil, have been proved to exist at the surface, and it appears inevitable that the deeper-beds of the Tertiary and the underlying Jurassic rocks are involved. The inclination of the axial plane of the older folding is not decipherable at the surface.

A magnetic survey of the area on behalf of Oil Search Ltd. subsequently made by J.M. Rayner, showed that no igneous intrusion was present at depth to account for the attitude of the surface rocks.

A further detailed geological survey of the Hundred of Blanche and the Burnda Anticline was carried out by E.A. Rudd. He showed that the structure is closed to the south, but flattens into imperceptible dips to the north. Outside this area and within the Hundred, the strata are apparently flat.

A shallow pilot hole, Bore B.M.R. No.231, and known as Knight's Dome No.1, was drilled in Section 170, to 311 feet.

|             |  |
|-------------|--|
| 0 - 17 feet | Subrecent surface accumulations of sand                                  |
| 17 - 80 "   | Polyzoal limestones and hard marls and basal calcareous grit (Janjukian) |
| 80 - 311 "  | Lignitic sands and clays (Anglesean)                                     |

The oil bearing horizon of the Lakes Entrance area is not represented in this bore.

Later, a bore known as Knight's Dome No.2; Bore B.M.R. No.232, was drilled in the crestal region of Knight's Dome, close to the Mount Gambier - Beachport railway. Total depth reached 2,013 feet. The bore proved 1,838 feet of beds of the lignitiferous series.

0 - 175 feet Polyzoal limestone series  
 175 - 2,013 " Lignitic sands and clays, carrying at intervals marine intercalations with fossils.

Testing operations carried out on sands between 1,825 - 1,869 feet and between 1,996 feet and bottom produced negative results.

(iv) Springs Bore; Bore B.M.R. No.233

A water bore drilled in Section 150 to a depth of 1,160 feet. The bore bottomed in dark grey lignitic and fossiliferous sandy clay, of the Anglesean Stage.

(g) Hundred of Caroline

Mapping by H.S. Lyne in 1923 was considered to have established the presence of a closed anticline in the extreme south-eastern corner of South Australia, near the Glenelg River.

Four bores have been drilled in the Hundred of Caroline.

| Section | Bore<br>B.M.R. No. | Bore<br>T.D. | Depth to base of<br>Polyzoal limestone |
|---------|--------------------|--------------|--|
| 337     | 234                | 1,226        | 533 feet                               |
| 336     | 235                | 1,824        | 506 "                                  |
| 543     | 236                | 1,561        | 527 "                                  |
| 598     | 237                | 839          |  |

Bores B.M.R. Nos. 234 - 236 were located close together and all three failed to penetrate the whole thickness of the series of alternating lignitic clays and sands. Bore B.M.R. No.237 was located 2.1/2 miles further south and was reported to have been abandoned in yellowish-brown sand underlying the polyzoal limestone and marl. Bores B.M.R. Nos. 234 - 236 bottomed in the lignitiferous series underlying the Janjukian polyzoal limestone.

It has been suggested that the results of these bores showing little variation in the elevation of the base of the polyzoal series, prove that no anticlinal structure exists. The argument is not conclusive because in the distance of 2.1/2 miles between bore B.M.R. No.237 and the group of bores B.M.R. Nos. 234 - 236, there is room for a synclinal axis. In the area mapped by Lyne, it would be very difficult to get conclusive evidence of closure, but evidence obtained from the cliff sections of the Glenelg River shows that gentle folding does exist.

VictoriaGlenelg Region(1) The Goroke - Edenhope District

Little is known of the subsurface geology of this very important section of the Murray River Artesian Basin; that part of the County of Lowan situated south of the Little Desert and west of the Grampians. In general, the area which rises to approximately 600 feet above sea level, is fairly flat with low ridges separating valleys containing lakes and swamps.

The Goroke - Edenhope District is bounded on two sides by bed rock. Granite, Schists, diabases and acid lavas are exposed in the valley of the Glenelg River and in the lower sections of some of its short tributaries from the north, while Grampian sandstones and isolated patches of Ordovician sediments outcrop on the east. Most of the area is covered by Cainozoic sediments. Marine limestones, probably of Middle Miocene age, appear at the surface at isolated localities between Apsley and Pine Hills Station, about 6 miles northwest of Harrow, and are no doubt continuous with the limestones outcropping over the border in South Australia and in the County of Follett. The limestones northwest of Harrow rest directly on granite, which itself outcrops further south, without the usually intervening lignitic silts and sands. The basalt flows (Newer Basalt) overlies the marine limestones near the confluence of Kadnook Creek, and the Glenelg River.

No complete geological examination has yet been made of any bores drilled in the Goroke - Edenhope District. A large part of the district is covered by Recent to Pleistocene silts, sands and fine gravels, the latter occurring at the base and becoming gradually finer upwards. Fossiliferous Werrikooian (Upper Pliocene) and Kalimnan (Lower Pliocene) deposits are known to exist, but there is little information as to their thickness or nature. Over a large section of this district, it seems as though the polyzoal limestones of Middle Miocene age, have been replaced, due to lateral variation, by clays and marls. Hence, throughout the district, the facies is noted to vary from limestones to marls and clays, each containing fossil assemblages which differ somewhat from each other but which indicate the same age. The fossiliferous clays are underlain by sediments described as black clays, which are thought to be the equivalent of the lignitic clays and sands found elsewhere beneath the bryozoan limestone.

Of the numerous bores drilled for water in the district, five have been selected for reference.

| Parish        | Bore<br>B.M.R. No. | Bore<br>T.D. | Remarks  |
|---------------|--------------------|--------------|--|
| Nurcoun       | 49                 | 364          | Bottomed in Tertiary limestone                           |
| Mortat        | 50                 | 700          | Abandoned in clays; no limestone                         |
| Charam        | 51                 | 140          | At 140 feet, mixture of Kalimnan and Werrikooian fossils |
| Harrow        | 52                 | 70           | Bottomed in granite                                      |
| Connewirrecoo | 53                 | 63           | Limestone, sands and gravels.                            |

Bore B.M.R. No.50 was put down on Pleasant Banks Station, about 4 miles west of Goroke. Some 600 feet of Tertiary Clays were penetrated in this bore; limestone, however is struck at less than 100 feet from the surface, only about 1 mile to the west, thus showing the lateral variation that is possible. The deep bores put down at Naracoorte and Bordertown proved that the lignitic series contained coarse sand and gravel beds. No similar coarse beds have as yet been struck in the Goroke - Edenhope District. Bore B.M.R. No.51, sunk at Maryvale, about 12 miles south of Goroke, bottomed in a marine bed containing fossils of Werrikooian and Kalimnan age. A number of shallow bores were drilled on Pine Hills Station, in the Parish of Harrow. Those to the south of the homestead bottomed in granite at very shallow depth.

In that portion of the County of Borung included in the area under review, very few bores have been sunk. Two bores put down in the vicinity of Green Lake cut fossiliferous lignitic beds at approximately 150 feet beneath the surface.

## (2) County of Dundas

Numerous bores have been drilled by the Mines Department in the Parishes of Carapook, Coleraine, Hilgay and Muntham. The bores passed through a shallow cover of Cainozoic clays, sands and gravels, and then entered the Jurassic sandstones and shales containing in places, thin seams of bituminous coal, at depths ranging between 10 - 38 feet. All the bores in these parishes bottomed in Jurassic sediments.

A brief summary of the bores is shown below:

| Parish    | Bore<br>B.M.R. No. | Mines Dept.<br>Name | Bore<br>T.D. | Top of<br>Jurassic |
|-----------|--------------------|---------------------|--------------|--------------------|
| Carapook  | 83                 | Carapook 1          | 410          | 34 feet            |
| "         | 84                 | " 2                 | 419          | 16 "               |
| Muntham   | 85                 | Muntham 1           | 593          | 38 "               |
| "         | 86                 | " 2                 | 784          | 37 "               |
| "         | 87                 | " 3                 | 694          | 28 "               |
| "         | 88                 | " 4                 | 470          | 32 "               |
| Coleraine | 89                 | Coleraine 1         | 538          |                    |
| "         | 90                 | " 2                 | 764          |                    |
| "         | 91                 | " 3                 | 735          | 23 "               |

| Parish | Bore<br>B.M.R. No. | Mines Dept.<br>Name | Bore<br>T.D. | Top of<br>Jurassic |
|--------|--------------------|---------------------|--------------|--------------------|
| Hilgay | 92                 | Hilgay 1            | 528          | 12 feet            |
| "      | 93                 | " 2                 | 60           | 23 "               |
| "      | 94                 | " 3                 | 54           | 24 "               |
| "      | 95                 | " 4                 | 43           | 19 "               |
| "      | 96                 | " 5                 | 65           | 12 "               |
| "      | 97                 | " 6                 | 116          | 17 "               |
| "      | 98                 | " 7                 | 70           | 14 "               |
| "      | 99                 | " 8                 | 70           | 29 "               |
| "      | 100                | " 9                 | 177          | 10 "               |
| "      | 101                | " 10                | 145          | 12 "               |
| "      | 102                | " 11                | 96           | 19 "               |
| "      | 103                | " 12                | 154          |                    |

(3) County of Follett

(a) In the eastern part of the Hundred of Comaum, County of Robe, there is an elevated area that extends eastwards into the Parish of Langkoop, County of Follett, which appears to be either a structural dome or horst. Its relationship to the lower country has not been determined by a series of boreholes, although one borehole, Bore B.M.R. No.153, was drilled near Comaum at a site near Lake Cooie, a mile to the east of the South Australian border and 36 miles to the north-west of Casterton. T.D. 1,171 feet.

0 - 132 feet      Superficial deposits  
 132 - 509      "      Polyzoal limestone series, glauconitic in the upper part  
 509 - bottom      Jurassic coal measures

The site is on somewhat elevated ground, which, it was thought, might correspond with doming in the underlying rocks. The striking at 509 feet of the Jurassic surface, which lies at 1,348 feet below sea level in the Robe burre and much lower still beneath Portland, shows that there is a considerable rise towards this part of the country, both from the west and from the southeast. Such a rise towards the plunge of the old rocks from the Victorian Highlands is normal, however, and there is no evidence for local doming.

(b) Two bores have been sunk in each of the Parishes of Casterton and Bahgallah. After passing through shallow deposits of superficial clays and sands, the bores penetrated and bottomed in the Jurassic coal measures. The bores are summarised as below:-

| Parish    | Bore<br>B.M.R. No. | Mines Dept.<br>Name. | Bore<br>T.D. | Top of<br>Jurassic |
|-----------|--------------------|----------------------|--------------|--------------------|
| Casterton | 81                 | Casterton 1.         | 794          | 36 feet            |
| "         | 82                 | " 2                  | 750          | 25 "               |
| Bahgallah | 112                | Bahgallah 1          | 268          | 82 "               |
| "         | 113                | " 2                  | 290          | 72 "               |

## (c) Scout boring around Parish of Dartmoor

A number of Government scout bores were put down around Dartmoor, and their locations are shown upon the detailed geological parish plan published for that district. These bores in general, proved the presence of the lignitiferous series at shallow depth beneath the polyzoal limestone. None of these bores penetrated the full section of the lignitiferous series. In Dartmoor 1 bore, pyrites has been recorded in most of the samples between 494 feet and bottom at 564 feet. Fossils were scarce in the samples from this bore, but some minute foraminifera were present.

A Summary of the Dartmoor bores drilled by the Mines Department is given below.

| Bore<br>B.M.R. No. | Mines Dept.<br>Name | Bore<br>T.D. | Limestones,<br>Marls & Clays | Lignitic<br>Sands & Clays |
|--------------------|---------------------|--------------|------------------------------|---------------------------|
| 115                | Dartmoor 1          | 564          | 0 - 24 feet                  | 24 - 564 feet             |
| 116                | " 2                 | 102          | 0 - 102 "                    |                           |
| 117                | " 3                 | 115          | 0 - 115 "                    |                           |
| 118                | " 4                 | 224          | 0 - 98 "                     | 98 - 224 "                |
| 119                | " 5                 | 48           | 0 - 30 "                     | 30 - 48 "                 |
| 120                | " 6                 | 182          | 0 - 176 "                    | 176 - 182 "               |
| 121                | " 7                 | 100          | 0 - 26 "                     | 26 - 100 "                |
| 122                | " 8                 | 96           | 0 - 77 "                     | 77 - 96 "                 |
| 123                | " 9                 | 34           | 0 - 32 "                     | 32 - 34 "                 |
| 124                | " 10                | 103          | 0 - 96 "                     | 96 - 103 "                |
| 125                | " 11                | 88           | 0 - 84 "                     | 84 - 88 "                 |
| 126                | " 12                | 71           | 0 - 68 "                     | 68 - 71 "                 |
| 127                | " 13                | 102          | 0 - 27 "                     | 27 - 102 "                |
| 128                | " 14                | 215          | 0 - 211 "                    | 211 - 215 "               |
| 129                | " 15                | 151          | 0 - 151 "                    |                           |

(d) At a site in the southwest corner of Crown Allotment 3-A, in the Parish of Malanganee, the Mersey Valley Oil Company drilled a bore known as Mumbannar No.1 (Bore B.M.R. No.154), to a depth of 1,100 feet. The bore passed through 800 feet of the polyzoal limestone series and thence through 300 feet of beds of ~~the~~ lignitiferous series.

(e) In 1926, the Point Addis Company drilled a bore, (Bore B.M.R. No.155), at a site in the Parish of Palpara, about 2 miles east of the South Australian border, to a depth of 1,170 feet.

0 - 754 feet Polyzoal limestone  
754 - 1,170 " Lignitic sands and clays

(f) Nelson Bore; Bore B.M.R. No.139

The Government bore known as Nelson 1 drilled at Nelson township, in the Parish of Glenelg, reached a depth of 7,305 feet. When drilling operations ceased, the bore had proved 7,299 feet of Tertiary sediments in the southwestern corner of Victoria, and palaeontological evidence has shown that the bore was still in sediments of Middle Miocene age.

Three stages of the Middle Miocene are represented in the bore:-

- (i) Balcombian Stage (basal portion) at 108 feet
- (ii) Janjukian Stage, represented by 864 feet of fossiliferous limestones, marls, and calcareous grits, from 112 feet down to 976 feet. Beds belonging to this stage include calcareous and fossiliferous grits; white to grey bryozoal marls; bryozoal limestones; dolomitic limestones and flints.

Three lithological and palaeontological zones have been recognised:-

- (1) The topmost zone extends from 112 - 625 feet and contains friable, bryozoal marls and limestones, and hard, pink dolomitic limestones and grey flints. The most important lithological types in this zone are the dolomitic limestones and flints. Similar rock types are well known in surface deposits in southeastern South Australia. The topmost

bed of the Janjukian in the bore is regarded as being at 112 feet.

- (2) The middle zone which occurs from 635 - 812 feet is comprised of grey to white bryzoal marls.
- (3) The lowest zone extends from 815 - 976 feet and is represented by calcareous sandstones and fossiliferous grits. From 939 - 976 feet these grits and sandstones contain abundant brown glauconitic grains. These glauconitic sandstones, though different in hand specimen from those at the base of the Janjukian in bores in the Lakes Entrance area, are apparently of similar composition and are referable to the same stratigraphic horizon.
- (iii) Anglesean Stage, represented by 6,316 feet of carbonaceous sandstones and shales from 989 feet to bottom at 7,305 feet. This is the greatest thickness yet proved for the stage in the area. Prior to the drilling of the Nelson bore, the greatest recorded thickness was in Knight's Dome No.2 bore where 1,933 feet were proved before drilling operations ceased. The lithology of these beds varies from dark to light grey micaceous and carbonaceous sandstones with foraminifera to moderately hard dark grey shales and sandstones with plant remains. The greatest depth at which there is evidence of marine conditions is 5,304 feet, where the typical Anglesean foram Cyclamina is present. An assemblage of foraminifera, bryozoa, fragments of mollusca, ostracoda and fish teeth is present in an unconsolidated sandstone at 1,924 - 1,943 feet. A similar assemblage was met with in Knight's Dome No.2 Bore, at the depth of 1,980 - 1,995 feet in similar unconsolidated sandstone, and at 2,110 feet in the Associated Oil Company's bore.

(4) County of Normanby

(a) A number of bores have been drilled by the Mines Department in the Parishes of Merino, Mocambo and Sandford. As in the case of the Carapook, Coleraine, Hilgay, Muntham, Casterton and Bahgallah bores, these bores entered the Jurassic coal measures at shallow depth. The bores are summarised below:-

| Parish    | Bore<br>B.M.R. No. | Mines Dept.<br>Name | Bore<br>T.D. | Top of<br>Jurassic     |
|-----------|--------------------|---------------------|--------------|------------------------|

(b) Portland Bores

The records of the two bores drilled at Portland in the eighteen nineties, apparently for coal, are rather unsatisfactory. The bores which were numbered Portland 1 (Bore B.M.R. No.140) and Portland 2 (Bore B.M.R. No.141), reached total depths of 2,265 feet and 1,505 feet respectively. The succession throughout was mainly calcareous. Much glauconite was recorded between 2,040 feet and 2,065 feet. These records suggest an important thickening of the marine rocks above the lignitiferous series rather than a passage into marine calcareous facies of the time equivalent of the lignitiferous series itself. The basal glauconitic rocks would be correlated with the oil-bearing glauconitic rocks of Lakes Entrance.

One mile north of Portland township, Thos. Borthwick and Sons put down a water bore (Bore B.M.R. No.142) to a depth of 622 feet. In this bore, basalt was encountered from 0 - 106 feet, and limestone followed, to bottom.

(c) Hamilton Bores

Several bores put down for water at or near Hamilton, proved the extension of marine Tertiary rocks beneath the Newer Basalt. The bores proved the presence of not less than 250 feet of the polyzoal series. One bore was sunk by the Mines Department in the Parish of Yulecart (Bore B.M.R. No.151) to a depth of 252 feet. Limestone and calcareous beds were encountered from 4 feet to bottom.

(d) Heywood Bores

Eight shallow bores were drilled by the Mines Department in the Parish of Heywood. These bores penetrated shallow depths of soil, sand and clay, before entering the Tertiary polyzoal limestones and marls.

(e) Tahara Bore; Bore B.M.R. No.152

This bore penetrated the Jurassic coal measures at 7 feet and remained in this series to bottom at 422 feet. The beds consisted of carbonaceous sandstones and mudstones and a few thin calcareous sandstone bands.

Wimmera Region

The Murray River Artesian Basin includes the major portion of the Wimmera Region. Bedrock is exposed along the southeastern and eastern margins of the region.

Bores drilled in this region which is included in the County of Lowan, show a notable thinness of Pliocene clays overlying the Miocene limestones. The maximum thickness of these clays is 45 feet, but they are less than 10 feet thick in most bores. No clays are found at this horizon in bores near the South Australian border (Bores B.M.R. Nos. 1 & 3) nor in the adjacent bores in South Australia.

Of the numerous bores drilled for water in the region, 13 have been selected and are listed below:-

| Bore<br>B.M.R. No. | Name          | Bore<br>T.D. | Series<br>Kalimnan | Series<br>Polyzoal | Series<br>Lignitic | Bedrock   |

(a) Netherby Bore; Bore B.M.R. No.10

|                |   |
|----------------|---|
| 248 - 660 feet | Polyzoal limestone  |
| 660 - 978 "    | Lignitic sands and clays                                  |
| 978 - 2175 "   | Sandstones, shales and conglomerates Upper-Palaeozoic (?) |
| 2175 - 2200 "  | Porphyry  |

(b) Dimboola No.1 Bore; Bore B.M.R. No.13

This bore is rather different from the general Murray River Artesian Basin bores and reveals:-

- (i) a great thickness, 206 feet, of fossiliferous marine clays underlying a thin band of gritty limestone
- (ii) the ligneous series represented by only 26 feet of silts and sands
- (iii) bed rock at a depth of 370 feet beneath the surface, possibly indicating a buried ridge.
- (iv) bed rock identified as diabase, probably of Cambrian age.

It is possible that this bore is located over a buried ridge, which extends northwards into the County of Weeah. An anticline formed in the Tertiary sediments deposited over this buried ridge may be the dividing line between freely flowing water to the west and partially stagnant water of much higher salinity to the east. According to Miss Crespin, the following stratigraphical horizons are present in the Dimboola No.1 bore:-

|   |             |
|---|-------------|
| Recent to Pleistocene                           | 3 - 61 feet |
| Upper Pliocene                                  | 61 - 80 "   |
| Mixed (?) Middle Pliocene<br>and Middle Miocene | 80 - 111 "  |
| Middle Miocene (Balcombian<br>Stage)            | 111 - 370 " |
| Palaeozoic                                      | 370 - 379 " |

It will be seen that both Upper and Middle Pliocene sediments occur, while beds of Kalimnan age (Lower Pliocene) are absent. The dark sands and silts underlying the Balcombian clays also contain typical Balcombian fossils and are therefore, not referable to the Anglesean, with which the lignitiferous series is correlated elsewhere in the Murray River Artesian Basin. It is possible that in the marginal areas sediments being deposited differed from those being laid down in the deeper central portion of the basin.

-----

### CONCLUSIONS

It may be assumed that any oil accumulations which may exist in the area, are likely to be associated with one of the following sets of conditions:

- (a) a closed anticline in which the oil-bearing horizon is under adequate cover.
- (b) a fault developed before the tilting of the basement was far advanced, along which the oil-bearing horizon is truncated up-dip, against impervious rocks.
- (c) a shore line belt in which the oil-bearing horizon resting directly on the basement is overlapped and so sealed up-dip by impervious rocks.
- (d) a "buried hill". A slight local irregularity in the surface of the basement, or an area of whose rate of subsidence was somewhat slower than that of the surrounding parts of the basement, upon which sediments have built up, could provide the required conditions. Such an irregularity might not be reflected at all at the surface, or in the upper parts of the Tertiary sequence, since such a structure would be more pronounced at depth than near the surface, and might therefore, escape detection altogether in scout bores drilled to the Miocene palaeontological markers.
- (e) an igneous intrusion, against which the oil-bearing horizon is tilted.

It can be stated that little hope remains that condition (a) is present in the area. It is improbable that an important closed structure in the Tertiary rocks would have failed altogether to reveal itself in the topography or surface geology. A program of geophysical surveying and scout boring may reveal the presence of a concealed structure.

Surface geological surveys show little reason to expect the presence of faults suitable to act as structural traps. The possibility that faults affecting the basement and the lower parts of the Tertiary rock sequence and possibly Jurassic, are present, but have been concealed by later deposits, remains open, and could be tested by geophysical surveys.

It is possible that oil-bearing horizons may exist in both the Polyzoal and Lignitiferous Series of the Tertiary, since this latter series contains marine intercalations throughout. It can be stated that reservoir sands and cover rocks in the lignitiferous series are numerous, and offer suitable conditions for the accumulation of oil. Marine sediments have not been found in the Jurassic rocks, however, so these fresh-water sands cannot be regarded as a source of oil.

It is thought that if oil exists in the region then some positive sign of it would have been found in some of the numerous bores, both for water and oil, so far drilled in the Murray River Artesian Basin. In the wide region to the north of the Naracoorte - Kingston railway, numerous bores have been drilled in search of water, but no sign of petroleum has been recorded from the boreholes. South of the railway, there has been considerable boring for oil, but no positive signs have so far been reported. Neither has a sign of oil been reported at any one of the volcanic vents, nor along the course of the Tartwaup Fault. It has been shown, too, that throughout the area generally, there is a copious and active movement of underground water towards the sea. Such conditions do not favour the ready accumulation of oil, although structural traps which are not known at the present time, may exist.

Most of the area has now been covered by an aerial photographic survey; this should be followed by a detailed geological survey of the area not covered to date, where such a survey is thought to be warranted, and finally, a geophysical survey of the region chosen from the results of the previous surveys is recommended, with a view to -

- (a) obtaining the general configuration of basement
- (b) determining the depth of basement
- (c) delineating any reflected structures suggested by (a) above
- (d) delineating other domed or anticlinal structures.

-----

## SUMMARY AND RECOMMENDATIONS

No detailed geological reports of the area have been published. Area under review is regarded as the southern extension of the Murray River Artesian Basin. The Basin is generally made up of Recent and Tertiary formations resting on a basement of Pre-Cambrian or Jurassic rocks.

The region is generally surfaced by a thin veneer of sand, travertine and dune limestone of Recent to Pleistocene age. Pliocene fossiliferous limestones occur in places and these are underlain by polyzoal limestones and flint beds of Middle Miocene age. (Balcombian and Janjukian Stages). The polyzoal limestones attain a thickness of more than 2,100 feet at Portland.

The Janjukian limestones are underlain by a series of lignitic sands, clays and gravels, containing marine intercalations and assigned to the Anglesean stage of Lower Middle Miocene age. These beds attained a known thickness of 6,316 feet in the Nelson Bore.

Greenish-grey shales and fine grained argillaceous sandstones containing thin seams of bituminous coal, outcrop in the Casterton- Coleraine district, and are met in several bores as far west as the Robe bore. The series is of fluvio-lacustrine origin, and is of Jurassic age.

Tillite, of Permo-Carboniferous age, has been recorded at 503 feet, in a bore drilled in the Coorong district.

Ordovician sandstones, shales, slates and mudstones outcrop along the Glenelg River in the Parish of Dergholm.

Cambrian granites also outcrop along the Glenelg River in the same Parish.

Pre-Cambrian granites, sandstones and quartzites outcrop as inliers in the area east of the Coorong and also in the Upper Glenelg valley.

At Alfred Flat, in the Coorong district, bores showed Recent and Tertiary sediments overlying Pre-Cambrian bedrock at shallow depth.

In the Kingston area, Pre-Cambrian slates were penetrated at shallow depths beneath Tertiary sediments.

Near Robe, a bore proved 1,475 feet of Tertiary sediments overlying the Jurassic coal measures.

A bore at Knight's Dome proved 175 feet of the polyzoal limestone series, and 1,838 feet of the lignitiferous series.

Bores in the parishes of Casterton, Carapook, Muntham, Coleraine, Hilgay, Merino, Sandford, Bahgallah and Mocambo struck Jurassic sandstones beneath a thin cover of Cainozoic clays, sands and gravels.

Bores in the Parishes of Dartmoor and Glenelg struck the two main Tertiary series, Janjukian limestones and Anglesean lignitic clays and sands.

Bores in the Parishes of Portland, Heywood and Yulecart penetrated soil, sand and clay, before entering Tertiary limestones and marls.

In the southern part of the area, the Tertiary formations are almost universally horizontal. Geological surveys for structures have been further hampered by the surface accumulations covering the Tertiary formations.

Most of the area has now been covered by an aerial photographic survey; it is recommended that this be followed by a more detailed geological survey of the area not covered to date, where such a survey is thought to be warranted, and finally, to assist in the interpretation of subsurface structural conditions, a geophysical survey of the area has been recommended:

- (i) a regional gravity survey
- (ii) a seismic survey of the localities where the gravity survey showed anomalies

In connection with the seismic survey, it is further recommended that:

- (i) use be made of the open bore hole at Nelson
- (ii) one profile be run from a bedrock inlier in the Coorong District to the Kingston area
- (iii) the profile be continued south to Robe
- (iv) a detailed survey be carried out of the area bordered on the north by a line running through Robe to Casterton; on the east by a line through Casterton to Portland; and on the south and west, by the coastline.
